D

ONLINE POSTGRADUATE COURSE REGISTRATION AND PAYMENT SYSTEM AT FSKTM, UM.

A Dissertation Submitted To The Faculty Of Computer Science And Information Technology University Of Malaya

By

SEE CHUN KIAT

In Partial Fulfillment Of The Requirement For The Degree Of Master Of Information Technology

October 2002

ABSTRACT

An Online Postgraduate Course Registration and Payment System is developed for postgraduate students in the Faculty of Computer Science and Information Technology (FSKTM), University of Malaya (UM). It is a Web application development. The system is developed to facilitate student online course registration and payment of fees. The system overcomes the queuing problem during the course registration and fees payment. UM administrators can view, delete and update the course registration, student, and administrative record through the system. ASP (Active Server Pages) is used to develop the system. Microsoft Access 2000 is used to store the student database.

ACKNOWLEDGEMENT

I would like to thank my supervisor, Associate Professor Dr.P.Sellappan, who has given me heipful advice throughout my project. It is only with his encouragement and support that I am able to complete this project.

Further thanks to all the general staff at the Faculty of Computer Science and Information Technology, especially Miss Agnes, for their generous help wherever possible.

1.0 INTRODUCTION

From E-Connection (Internet) to E-Contents (Web Portals) to E-Commerce, the world is witnessing successive milestones of ongoing digital revolution - the former being pre-requisite of the latter. The digital revolution leading to information society is silently but surely triggering transformation of social infrastructure within the nation for its socio-economic development as well as acting as a vehicle to integrate itself as a part of global networked/digital economy. (Arvind Panagariya, 1999)

While there is no single globally accepted definition of E-Commerce, it is gradually leaning towards "goods and services transacted over Internet". E-Commerce is thus a new way of conducting, managing and executing business transactions using modern Information Technology. The Internet provides access 24 hours a day, seven days a week – any time anywhere. Thus, time and place are no longer the binding factors. Electronic Commerce builds on the structures of traditional commerce by adding the flexibility offered by electronic networks. This facilitates improvement in operations leading to substantial cost savings as well as increasing competitiveness and efficiency through the redesign of traditional business. (Kalakota, Ravi & Whinston A, 1996)

Payment gateways are credit card processing services that allow organizations to authorize and process credit card orders online in real time. Payment gateways act as a bridge between the merchant's website and the financial institutions that process the transaction. Payment gateways are an integral part of e-commerce. Existing brick and mortar companies may find that they can target a new market by selling online. Whether or not a business becomes more competitive by providing online sales will depend on the marketing mix, product, place, promotion and price. The marketing mix will help to determine whether the particular business will be competitive. (Kathy Brown, 2000)

Online course registration meaning students can register for classes online via a custom, Web-based registration application. Students can view and choose the list of all the online courses offered each semester.

1.1 Introduction of the Project

Online course registration and payment system is yet to apply in University of Malaya (UM), and other local universities in Malaysia as well. But, it is popular in European countries.

Online payment means using credit card (visa or master card) to pay fees for the course they have registered online. But, students can also directly pay cash to UM Bursar's Office after they have registered their course online. All fees are payable after online course registration and registration is not complete until these fees have been paid. Fees are subject to change prior to each semester. All the payment record

such as mode of payment, credit card type, credit card number, expire date of the credit card, name of the card holder and address of the card holder will be stored in the database.

UM Bursar's Office will process students' credit card information immediately for an authorization after the students have made the online course registration. This means that UM Bursar's Office will contact the bank electronically and verify that credit card information students have provided matches the credit card information where their credit cards are mailed. If the information they have provided is different from information that bank has provided to UM Bursar's Office, the course registration will be delayed or canceled. UM Bursar's Office will resolve problems that may arise from the address verification process by contact the bank or the student. UM Bursar's Office will contact the local police department to report all fraudulent fees payment.

Online Postgraduate Course Registration and Payment System is implemented for the postgraduate students in Faculty of Computer Science and Information Technology (FSKTM) in University of Malaya. This project is done for postgraduate students in Faculty Computer Science & Information Technology, as the scope is too broad if it is expanded for all students in UM. The system will cater for students in Master of Information Technology, Master of Computer Science, Master of Library and Information Science, Master of Software Engineering, and PhD's.

Besides registering online for their courses and make payment with this system, students can also view their latest timetable for the semester. For administrators, they can view, delete and update students' record, course information, administrators' information and registration report. User ID and password are needed for both students and administrators to access into the online course registration and administrator site.

1.2 Problem Statements

The current system of course registration and fees payment in UM shows inefficiency in the method of course registration and fees payment. UM allocates specific windows of time each semester for different populations of students to register for classes. The largest window is for the courses that are popular, and it accommodates nearly 400 to 1000 students trying to register simultaneously for that particular course. Therefore, every time during the registration period, course registration application will become overloaded, and some students experienced delays in registering for courses.

In addition, students have to wait in a long queue at the bank to pay their fees. After that, they have to go to UM Bursar' Office to submit the bank statement to prove that they have paid the fees. The students have to queue up again. Then, students have to endure another queue to submit their course registration form in the faculty's office. On top of that, if the students want to change courses, UM staff will need to do a lot of work like checking all the information in the forms is correctly written by the students, check the redundancy of courses that register by students. After that, the staff will submit all the forms to the person in charge in order for him to record the new information into the database.

With the Web-based registration application, these problems are resolved. The students can access to the Web site to pay fees online and register their courses online.

1.3 Mission

The purpose of Online Postgraduate Course Registration and Payment System is to overcome the queuing problem and paperwork during course registration. It will facilitate faster course registration and payment process.

1.4 Objectives

This project has the following objectives:

Online course registration and payment system can save students' and UM administrators' time in course registration and fees payment.

- Online course registration and fees payment will lessen queuing problem in Administrators Office, Bank and UM Bursar's Office.
- Online course registration can avoid unnecessary hassle during course registration and increase the effectiveness of course registration process.
- Online course registration will decrease the workload of the UM administrators and staffs during and after the registration.
- Online payment using credit card will make the fees payment process faster rather than paying in bank or UM Bursar's Office.

1.5 Project Scope

The scopes of the project are as follows:

- Develop a web application system for FSKTM postgraduate students to register their course and pay fees online.
- Implement course fees calculation facility for students during the process of course registration in the system.
- Provide the latest online timetable for students.
- Provide UM an administrative facility, where UM administrators can view, delete and update students' records, course information as well as administrators' records on the web.
- UM administrators can see the registration report after students register online.

1.6 Expected Outcomes

The final outcome of using this system is expected to have the following features.

- A web application system that can register students' course and pay fees online.
- A web application system that enables UM administrators to view, delete and update course information, student records, and administrators information.
- A database system that will store and organize all records pertaining to the registration, such as the students personal information, administrator records, course registered by students, fees, and payment information.
- Automatic calculating facility for students to find out how much they need to pay.
- UM administrators can check the registration report after students register their course online.

1.7 Report

The purpose of this report is to document all the essential information gathered and used to develop this system. It covers several instructional design phases that include analysis, design, development, testing, implementation, and evaluation phase of the system. This report is divided into 6 chapters. A brief synopsis of each chapter is listed below. **Chapter 1: Introduction** gives overview of developing the system, problem statements, project mission, objectives, project scope, and expected outcomes of the system.

Chapter 2: Literature Review serves to build up the basic knowledge of the setting up of the whole system, with the involvement of various softwares. For a better knowledge of developing the system, research of case studies also have been done. Software preference is also discussed, and comparison between softwares is done to choose the most suitable one.

Chapter 3: System Analysis focuses on the methodology of developing the system, project schedule, requirement analysis, where functional and non-functional requirements are described, run time requirement and also data flow diagram (DFD).

Chapter 4: System Design focuses on architectural design, system architecture, database design, and user interface design.

Chapter 5: System Testing and Implementation stresses on the implementation part and system testing.

Chapter 6: System Evaluations and Conclusions begin with various evaluation techniques. Technical problems, recommended solutions and future enhancement are also discussed here.

8

2.0 LITERATURE REVIEW

2.1 Interactive Features Through Internet

2.1.1 HTML (Hypertext Markup Language)

HTML is by far the most common document format on the World Wide Web. HTML is a form of SGML (Standard Generalized Markup Language), which is primarily concerned with structure, rather than layout or presentation styles. (Nadav Savio, 1997). Thus, though widely used, HTML does not support most of the page layout features found in desktop publishing applications. It does include tags that provide for some forms of presentation, such as tables, and tags to specify fonts and colors. However, these tags are bulky and require extensive coding. A major complaint against HTML is that it does not allow the precise positioning of text and images, as required in desktop publishing. Authors and publishers want greater control over layout so that they can create sophisticated publications that retain the same layout and look regardless of the configuration of a user's browser. Two developments, Cascading Style Sheets and dynamic HTML, have been designed to address these limitations of HTML. (Laura Lemay, 1996)

2.1.2 Cascading Style Sheets (CSS)

Cascading Style Sheets (CSS) address the problem of layout control, putting the power of desktop publishing into the hands of Web publishers. Authors can create pages that display precise margins, various font styles, measured white space around text and graphical elements, and other desktop publishing-like page formatting controls. In addition to helping authors create the exact layout they want for a page, Cascading Style Sheets allow them to apply a universal look and feel over an entire Web site without the work of inserting new tags and templates into each Web page. (Jeff Kozoris, 1997)

Features and advantages of Cascading Style Sheets:

- Provides precise control over margins, line spacing, element placement, colors, font faces, and font sizes
- Removes the need to re-type HTML style tags each time a new style is needed
- Ensures every user sees the same view regardless of the ways in which the browser's size and colors are configured
- Provides the ability to change the overall look of a Web page or even an entire site by changing a single style sheet.

Alternatively, style information can be contained in a separate, single file to which all relevant HTML files refer. Thus, when a change to a Web site's overall look and feel is desired, changes need only be made to the style sheet file. This aspect is a significant development for those who maintain extensive Web sites. Presently, a change in look and feel across a site requires that each HTML file be opened and the code modified. With CSS information in a separate file, the code changes take place once in a single file. (Que Corporation, 1997)

2.1.3 Dynamic HTML

Dynamic HTML is a combination of Cascading Style Sheets and a scripting language (such as Visual Basic script or JavaScript) that merges the actual HTML document with the style sheet. Using Dynamic HTML, developers will be able to create a Web page that can respond dynamically to user-generated events, such as mouse clicks, by expanding an HTML table, changing the attributes of a font, or moving a graphic across a page. All of this can be done without going to the server or relying on plug-ins or Java applets. (Levitt, J, 2000)

2.1.3.1 Data Binding

One of the key features of dynamic HTML is that the browser does the processing of effects locally, putting less strain on the server and speeding up load time. A very powerful example of this feature is "data binding." Currently, when a user interacts with a database, data are pulled from a system; tagged on the fly with HTML, then send to the user. If a user wants a different view of the data -- for example, sorted by author or by date -- he or she must make another call to the server which sorts the data, reformats it in HTML, and resends the data to the user. With the data-binding feature of dynamic HTML, all relevant data are sent to the user to be sorted, filtered, and modified repeatedly, without having to contact the server again. (Levitt, J, 2000)

positioning of elements on a page, a set of mutumedia controls for animation, approchannel flinging, and other effects and the ability to bind sets of deta to an HTML (organization, N, 1997)

2.1.3.2 Fonts

In both desktop and Web publishing, the availability of fonts is a major issue. Currently, Web authors are restricted to using fonts that are commonly present on users' systems. A feature of dynamic HTML is the ability to use virtually any font on a Web page without the need for end users to have it present locally. This feature allows a Web page to retain its intended look when a certain font is specified. The text will not revert to New Times Roman if the font is not present, as is currently the case with standard HTML.

2.1.4 Differences Between Netscape and Microsoft Version of CSS and Dynamic HTML

Netscape Communicator 4.0 supports Level 1 version of CSS (CSS1) under the name "JavaScript Accessible Style Sheets" (JASS), while limited CSS support is now available in Microsoft's Internet Explorer 3.0, to be known as "Dynamic HTML." Both the Netscape and Microsoft versions are recognized under the generic name of "dynamic HTML," with the lower case 'd.' In addition, each company has its own definition of dynamic HTML.

Microsoft defines DHTML as the HTML document object model a way to control the positioning of elements on a page, a set of multimedia controls for animation, alphachannel filtering, and other effects and the ability to bind sets of data to an HTML page. (Zelnick, N, 1997) Netscape, on the other hand, defines DHTML as HTML plus Netscape extensions, JavaScript, Java, and an object model for HTML documents. (Zelnick, N, 1997)

It is very important to note that CSS1 has not yet been coalesced into a common standard. As with earlier versions of standard HTML, Netscape and Microsoft have created their own, idiosyncratic features of dynamic HTML. Both have put forward these ideas to the W3C to be considered for the standard. This divergence causes problems: if these two major companies are developing different forms of dynamic HTML, elements of CSS Web will be browser dependent. This erodes the cross-platform compatibility that has allowed the Web to grow as wildly as it has.

Finally, dynamic HTML is supported only by Netscape Navigator and Microsoft Internet Explorer. There is currently no support for dynamic HTML in older Netscape and Microsoft browsers or browsers of a different type. When non-compatible browsers encounter dynamic HTML, all the information will be displayed, but without the new features. Without a common standard, authors face the possibility of creating three versions of their pages, one with Microsoft Dynamic HTML, one with Netscape JASS, and one without dynamic HTML at all.

13

basis for information exchange on the Internet), HTTP is an application protocol. Essential concepts that are part of HTTP include (as its name implies) the idea that files can contain references to other files whose selection will elicit additional transfer requests. Any Web server machine contains, in addition to the HTML and other files it can serve, an HTTP daemon, a program that is designed to wait for HTTP requests and handle them when they arrive. Web browser is an HTTP client, sending requests to server machines. When the browser user enters file requests by either "opening" a Web file (typing in a Uniform Resource Locator) or clicking on a hypertext link, the browser builds an HTTP request and sends it to the Internet Protocol address indicated by the URL. The HTTP daemon in the destination server machine receives the request and, after any necessary processing, the requested file is returned.

2.2 Web Application Development

Developing Web-based applications can be very different from other types of programming. Unlike normal client/server applications, web pages are stateless, which means that when the page is called, it grabs the data it needs, and then sends the document to us. A system that developed using Web-based applications will involve many interactive features such as insert, delete, and add features, dynamic database, shopping cart, visa or master payment gateway and others. (Eric A. Smith, 2000)

In traditional client/server development, a client application maintains a connection with its server component. Besides requesting and sending data, the client queries the server periodically to make sure the connection is still alive. If the server goes down, it will sense this and take the appropriate measures such as sending an error message to the user.

As a Web application developer, I have to deal with the short-lived memory of web servers, with the Internet being a connectionless network. When a browser requests a page, it is serve up and serve out. The server is not going to check and see whether the page and all of its components (graphic, sound and so on) are on the browser.

But ASP (Active Server Pages) and ADO (ActiveX Data Objects) are significant steps in dealing with these issues. It has a memory to "remember" user.

2.3 Database Server

The database server plays a vital role in Internet application development. The database server can be used to store, search, and retrieve information that is stored in a database. This same database that distributes information to Web users can also be accessed and maintained from or within the corporate walls. (Eric A. Smith, 2000)

When using the HTTP server as a connection utility to database servers, there is a slight shift in architecture that differs from traditional application development. For

example, when creating an online classified section for the local newspaper or mechanism that search for vehicles of a particular type. From an architecture perspective, this application will have three components: the requesting browser, the Web server, and the database server (see Figure 1). The browser is responsible for submitting query requests and displaying the results from the database. The Web server is responsible for the database, formatting the results into HTML, and delivering the HTML to the requesting browser. The database server is responsible for accepting requests from the Web server and delivering results back to the Web server.

17

Figure 1: When accessing database information from a Web browser, the Web server acts as the client to the database server

2.4 Database Management System (DBMS)

DBMS is the software that interacts with the user's application program and the database. Typically, a DBMS provides several facilities. It allows users to define the database, usually through a Data Definition Language (DDL). The DDL allows users to specify the data types, structures and constraints on the data to be stored in the database. (Scot Johnson, Keith Ballinger, Davis Chapman, 2000)

DBMS allows users to inserts, update, delete, and retrieve data from the database, usually through a Data Manipulation Language (DML). Having a central repository for all data and data description allows the DML to provide a general inquiry facility to this data, called a query language. The provision of a language alleviates the problems with file-based system where the user has to work with software management problems.

There are two types of DML, such as procedural and non-procedural, which we can distinguish according to the retrieval operations. The main difference between them is that procedural languages typically manipulate the database record by record. While non-procedural languages operate on sets of records. Consequently, procedural languages specify how the output of a DML statement is to be obtained, while non-procedural DMLs describe only what data is to be obtained. The most common type

of non-procedural language is the Structure Query Language (SQL). SQL is now both the standard and the *de facto* language for DBMS.

DBMS also provides controlled access to the database. For example, it may provide:

- A security system, which prevents unauthorized users from accessing the database.
- An integrity system, which maintains the consistency of stored data.
 - A concurrency control system, which allows shared access of the database.
 - A recovery control system, which restores the database to previous consistent state following a hardware or software failure.
- A user-accessible catalog, which contains description of the data in the database.

2.5 Data Access Interface Paradigm

2.5.1 ODBC (Open Database Connectivity) Data Source Administrator

ODBC is a programming interface that enables application to access data in database management system that uses Structure Query Language (SQL) as a data access standard. There are three major data sources in ODBC Data Source Administrator: System Data Sources, User Data Sources and File Data Sources. (Scot Johnson & Keith Ballinger, 1997)

In this project, I am using an ODBC File data source. An ODBC File data source allows us to connect to a data provider. The reason that I use File DSN is because it can be shared by users who have the same drivers installed.

On the other hand, Microsoft Access Driver has been used in the ODBC Data Source Administrator. Microsoft Access Driver is an ODBC driver that allows ODBCenabled programs to get information from ODBC data sources.

2.6 Client/Server Development

When developing a database-driven application, it will be a very rare case where many users do not access the database at the same time over a network or the Internet. This type of application is called client/server, and it refers to a system in which there is a client program that handles some tasks, and a server program that handles others. The Web is an example of a client/server application. The Web server handles certain tasks, such as finding the appropriate page, while the browser displays the page contents. With client/server database programming, there is, at the very least, a server where the database resides, and several client machines on which a client program is used to access the database server. (Scot Johnson & Keith Ballinger, 1997) When developing client/server systems, one must consider the tasks and processes that are performed by the server and the client. The very best application is a marriage of tasks between these two components.

Some of the tasks best suited for the client are as follow:

- Display of result sets from the database
- Simple data validation
- Gathering data before querying the database
- Formatting and filtering result sets form the database

Meanwhile, the server is often best used for these tasks:

- Complex data validation
- Indexing data
- □ Finding and returning result sets to the client
- Maintaining database integrity
- Managing transactions

2.7 Case Studies

2.7.1 Case Study 1

From the article written by Andrew Aird (2000), "E-commerce in Higher Education: can we afford to do nothing?" argues that the impact of e-commerce is beginning to

be felt in the non-commercial sector, and reveals the results of a survey of opinion taken after a recent web management workshop. With e-commerce emerging as the driving force behind commercial websites, its impact is beginning to be felt in the noncommercial sector. Those working in Higher Education, in particular, need to prepare carefully if we are to reap the rewards and avoid the pitfalls by establishing appropriate 'business' structures as well as refining technical and managerial approaches. Survey of the 76 Higher Education organizations who responded over 80% claim to have some kind of e-commerce system in place now or plan to by the middle of 2001. (E-commerce here is defined as having an online system for ordering and paying for goods or services, although the method of payment may not necessarily by credit/debit card.) In fact, 70% of the institutions surveyed will continue to use paper-based systems (such as invoice generation, follow-up cheque) rather than online transfer of funds. (Andrew Aird, 2001). Selling publications, payment of fees and alumni goods make up the largest categories of transactions (74%). Other uses included supplying advice and information (5%), sales of concert/theatre tickets and printing/photocopying charges. In many cases it was web staff (60%), although academic departments themselves show significant involvement (13%). Perhaps surprisingly, Finance Departments appeared to be involved in very few cases (6%). Only one institution surveyed had a project officer dedicated solely to e-commerce development. The survey also looked briefly at the online shopping habits of the individual respondents, with the aim of seeing how much our consumer experience might affect our approach as providers. Almost all (98%) of those who had bought goods or services online were satisfied, and most (92%) regarded this as a safe method of making payments. Incidentally, the most poplar sites used were Amazon (62%),

23

Easyjet (11%) and Go-fly, Expedia and Tesco equal in third place (4%). The survey contrasts sharply with figures given at the Parallel Session by John Williams, CEO of Trustmarque: Taking a world view, 25% of e-commerce transactions are never fulfilled, and 53% of online customers are concerned about security and privacy. Furthermore 'conversion rates' of visitors to buyers currently run at about 1.8%. Evidently the experience of e-commerce in Higher Education is more positive, and this may be an important starting point when planning or running such a system. The 'brand' of Higher Education Institutions (HEIs) already has much global credibility – no one suspects that HEIs is going to steal your identity or defraud your credit card, and they already have a reputation for providing 'quality'. This may help to reassure users in the future who may be paying substantial course fees online, or signing up to an expensive distance learning.

2.7.2 Case Study 2

A study to an article on web site http://www.oar.uiuc.edu/current/Default.htm/ shows that University of Illinois at Urbana-Champaign was implemented the UI Direct system for their students to register courses online. The UI Direct system will control access based upon registration time, class size, academic program, maximum credit limit, advising hold (if applicable), and encumbrances. This system has some drawback although the university's students can register their course online. For instance, UI Direct Assistance is available only from 8:30 a.m. until 5:00 p.m. Monday-Friday at the Records Service Center. If an advising hold has been placed on student's record, it must be removed before he/she can register. The students should

resolve all encumbrances as soon as possible. If they have an encumbrance on their record, access to UI Direct to drop or add classes will be blocked approximately three weeks prior to the first day of instruction. If the student has an encumbrance on their record as of 5:00 p.m. on the first day of instruction, their course registration for the term will be cancelled. The student can avoid having their course registration cancelled by resolving encumbrances. Besides that, using this system will facing the problem of fees payment by the students. It is because this system does not have the online payment gateway using visa or master card. UI Direct is a system to register for courses by computer. When the students do so, they agree to pay tuition and fees to the University according to the payment policies and schedules adopted by the Board of Trustees. If they wish to cancel their registration, and thus avoid payment of fees charges, they must do so by 5:00 p.m. of the first day of instruction. Furthermore, the lack of securities of the system is found. Unauthorized use of University of Illinois computer systems, data, or resources; unauthorized use of another individual's identification, account, or password; or an attempt to gain unauthorized access is prohibited by University policy and may constitute a violation of Illinois state law. Access to U of I Direct will be terminated if students are found to be making excessive unsuccessful registration attempts.

2.7.3 Case Study 3

Another study that has been done by Suffolk County Community College (SCCC) at http://www.sunysuffolk.edu/Web/VirtualCampus/ shows that this college is implementing two kinds of course registration and payment system, such as online

registration and payment system or by using the SCCC telephone registration and payment system. If the student wishes to use the telephone registration system, they need to gather the following information: the four-digit section number of the course they wish to take, the name of the campus offering the course, the semester that the course is being offered (use 1 for intersession, 2 for spring, 6 for summer, 9 for fall) and the nine-digit student ID. If the student registers their course online, during the first week of classes they have the opportunity to make changes to their schedule, which will not appear on their transcript. Students can accomplish this by going to the online registration and system or by calling the SCCC telephone registration system.

2.7.4 Case Study 4

A study that have been done by New Brunswick Distance Education Network Inc in Canada at https://www.sis-sia.gnb.ca/test/sis/ shows that before the organization/institution begins using the TeleCampus online registration and payment system (SIS - Student Information System), the organization/institution must be capable of accepting credit card payments. The organization/institution has to make sure that their business accounts are compatible with their PAYWAY Service. Once their business accounts are ready to accept credit card transactions, TeleEducation NB's TeleCampus SIS admin via email and request access to the system. At that point, the organization/institution will be configured in the Test SIS System. If they are not a NB Community College, an institution number will be automatically assigned (by the system) and the courses given course codes. These are used by the system to track the courses and students. Once the organization/institution supplied TeleCampus with the
information needed to track the courses and accept online payment, then they must configure their website to forward registration requests to the SIS. To do this, they simply must embed the application button or link in their page. Each application link must include the respective course code to TeleEducation. After a short testing period and approval of the registration process, TeleEducation will move the course information into the production SIS system. The testing, approval and moving phase may be as short as two days, or as long as they require. Organization/institution is now ready to accept online course registrations and payments.

2.7.5 Case Study 5

Students at Duke University's undergraduate, graduate, and professional schools register for classes online via a custom, Web-based registration application. Duke. (Cisco System, 2002). During registration for the spring semester 2001, Duke's online course registration application became overloaded, and some students experienced delays in registering for courses. At that time, the Web servers handling the registration application received requests through a round-robin Domain Name System (DNS) rotary. This system provided no mechanism to intelligently balance the workload and could not compensate for a "sick" or "dead" server. As a result, groups of students could be routed to a server that was performing slowly or was completely unresponsive. Duke had to stabilize the online registration system to increase performance and guarantee that every student would be able to register in a timely manner while also ensuring that each student's private data was protected. Duke University implemented the Cisco 11000 Series Content Services Switch (CSS) and

the Cisco 11000 Series Secure Content Accelerator (SCA) to enhance the performance of its online course registration application, guaranteeing 100 percent server availability and ensuring secure and successful online registration.

2.7.6 Case Study 6

In the article that wrote by Steve Patient, " Reducing Online Credit Card Fraud ", credit card company figures show that 90 per cent of consumers are reimbursed when their cards are used fraudulently, while 75 per cent of online retailers have to eat the cost when they're the victims of credit card fraud. There is currently no way to avoid this ludicrously high risk, though it can be reduced. (Steve Patient, 2002). Unfortunately, online payment remains a major area of Internet immaturity. Payment and data transfer security are allied problems. When buyer and seller meet physically to exchange money for goods, trust is less of an issue than when two entities deal blind online. Though buyers - rightly - distrust online credit card payments, merchants suffer more from credit fraud. This is because most online payment is by credit or debit cards, and the payment protocols for these were originally intended for face-toface sales where the cardholder and card are both physically present. Physical presence offers security based on a customer signature and card imprint. But the merchant is almost always responsible for losses when sales are made on a 'Cardholder Not Present' basis even when the vendor has obtained authorization from the card issuer.

2.8 Database Consideration

2.8.1 Microsoft Access

Microsoft Access is a relational database management system and can be used in a client/server or an n-tier architecture system. It provides intuitive and user-friendly interface to create a database easily.

2.8.2 Conclusion of The Database Consideration

For database development in this project, Microsoft Access 2000 will be chosen, as it has an easy-to-use visual interface. It enables users to group and sort data. It also can be upsized to SQL database when necessary in the future. Microsoft Access has a simple and complete development environment. Furthermore the cost is much lower compared to SQL Server 7.0. Therefore, using Microsoft Access will significantly reduces the development cost.

2.9 System Application Development Tools Consideration

After choosing the database (Microsoft Access 2000) that will be used in the system, the development tools for developing this system are considered.

29

2.9.1 Microsoft Visual Basic 6.0

Visual Basic 6.0 is a high-level visual programming version of BASIC. It is able to create a wide variety of component types, including Microsoft ActiveX dynamic link libraries (DLLs), ActiveX Controls and ActiveX Components for deployments in Intranets or the Internet. (Eric A.Smith, 2000)

Visual Basic has a native code compiler and offers the ability to develop ActiveX controls and DLLs; it is a good choice for just about any type of Windows application development. Visual Basic is particularly strong when it comes to file processing and the development of a database front end.

Visual Basic is probably the easiest development tool to use. The environment makes it very easy to build a user interface, and it is easy for just about any programmer to pick up. It is very strong for building database application, especially those that use Microsoft Access database.

2.9.2 Visual C++

Visual C++ is a good choice for building scientific and engineering applications. This is because it still has a large speed advantage over Visual basic when performing these types of tasks. One drawback is that designing a user interface with Visual C++ is not as easy, and developer has to know the C/C++ language in order to use it. Even with

native code compilation, for some application, Visual C++ will still have a hefty speed advantage compare with Visual Basic. Visual C++ has more multithreading ability than Visual Basic, which still remains rather limited in this area. (Eric A.Smith, 2000)

2.9.3 Active Server Pages (ASP)

ASP means to Web-based application development. ASP is a new technology from Microsoft that provides the capability for the Web server to process application logic and then delivers standard HTML to the client browser. The results can then be delivered to a variety of client-side Web technologies, such as standard HTML, ActiveX, Java, browser plug-ins and DHTML. In addition, ASP provides a powerful interface to develop programming logic that can be used to implement and distribute the information through applications across the Web. (Eric A.Smith, 2000)

2.9.4 Microsoft Personal Web Server

Microsoft Personal Web Server (PWS) is the answer to the personal information sharing and Web development needs. PWS is a desktop Web server that makes Web site setup quick and simple, from creating a personalize home page automatically, to drag-and-drop publishing of documents. (Eric A.Smith, 2000)

On the corporate intranet, Personal Web Server can be used to quickly share documents in their native format, or convert documents to HTML, and then use PWS to share them across different operating systems.

Because Personal Web Server supports Active Server Pages, it can be used as a development and testing platform for Web sites. Create the web site in the office or at home, and test it by using Personal Web Server, before hosting it on the corporate server or an Internet service provider.

2.9.5 Microsoft Visual InterDev 6.0

Microsoft's Visual InterDev is a development environment in which can create, edit, deploy and manage Active Server Pages. Visual InterDev combines a rich set of database connectivity tools, wizards, and design-time controls to increase the functionality and decrease the development time to build Active Server Applications.

The functionality of Visual InterDev can be categorize into four sections:

- File and source code management
- Database connectivity and live-design-time access
- Active Server Page functionality
- Client-side functionality

2.9.6 Conclusion of Development Tools Consideration

After surveying the above development tools, I decided that Microsoft Visual Basic 6.0 and Visual C++ is not suitable to use in this project. It is because Microsoft Visual

Basic 6.0 and Visual C++ is not suitable for web application development although it provides a flexible, extensible and friendly development environment to develop database application. Microsoft Visual Basic 6.0 and Visual C++ are only suitable for window application development. But, online postgraduate course registration and payment system is a web application system development.

The reasons I choose to use ASP because it is suitable for existing application developers who have some experience developing client/server applications. Therefore, the application developers can translate their existing experience developing applications into building robust, scalable, Web-based applications using ASP. Besides, ASP gives the ability to deliver more than just HTML. ASP can deliver HTML, client-side scripting, Web controls, and server-side processing and connectivity features. ASP scripts can deliver client-side scripts, such as *VBScript* and *JavaScript*, to be executed on the client's browser. In addition, ASP can also delivers wide range of Web functionality by acting as a transfer vehicle for ActiveX controls, Java applets and other Web components. ASP not only produce a dynamic HTML depending on the client request, but also provides the capability to tap into existing systems, such as databases, document retrieval services, mail servers, and other COM-based information servers.

ASP now act as a HTML interpreter that was once only accessible through native interfaces, such a Microsoft Exchange client, Lotus Notes client, or a customize Visual

Basic application. With the wide range of functionality, ASP act as a medium for porting existing applications to --- and building new applications for --- the Web.

Other than that, Microsoft Personal Web Server and Microsoft Visual InterDev 6.0 are also chosen to support my task.

2.10 Scripting Languages Consideration

Since I decided to use ASP as my development tool, therefore VBScript and JavaScript will be the scripting languages in my project. However, VBScript will be the scripting language that I frequently use in this project.

VBScript was initially created by Microsoft to be a lightweight scripting language to interpret users events triggered within the Internet Explorer browser. VBScript is actually created from Visual Basic for Applications (VBA), a pure subset of Visual Basic. VBScript can be used to create references to control HTML intrinsic object, ActiveX automation objects, ActiveX controls, and Java applets.

Besides, JavaScript is also a lightweight, interpreted scripting language that provides the same functionality as its VBScript counterpart. The syntax of the JavaScript languages is similar to C. JavaScript is a product of Netscape Communications Corporation and Sun Microsystems Inc. From the security point of view, VBScript was initially designed to be a safe, interpreted language to be executed on the Internet Explorer browser. Designed to minimize possible security violations to the client's file and subsystems, VBScript prevents any file input/output and prevents access to the client's operating system. To further prevent destructive intentions, VBScript uses only one data type, *Variant*. (Johnson, S. & Ballinger, K. & Chapman, 1997)

Finally, I will use HTML (Hypertext Markup Language) and Java Script in web or system design while the server scripting is developed using VB Script.

2.11 Browser Consideration

ASP only supports Microsoft Internet Explorer's server. It does not support Netscape Communicator's server. The Netscape Communicator's server could not understand the ASP syntax. Therefore, the Microsoft Internet Explorer browser is being used in my project.

3.0 SYSTEM ANALYSIS

This chapter intents to ascertain the functional and non-functional requirements of this project. System development methodology and project planning will be discussed here. Besides that, the determination of the programming language, database and hardware is needed. A mixture of various kinds of tools will be determined and used to build this project.

3.1 Methodology

There are many types of software process models in software engineering. The software model process selected for this project is software prototyping. This model wills clearly shows what goes on during the development process, and it suggests developing the sequence of events the developers should encounter. (Sommerville, 2002)

Prototyping is a worthwhile technique for gathering specific information before a "real" system is being developed. It enables the developer to create a model of the system and refine it into a newer version, or discard and start creating another model that will fulfill the developer's and user's needs.

Prototyping allows more flexibility to meet with new requirements and the addition of more innovative features. The prototyping model is shown in Figure 2.

Figure 2: Prototyping Method

Prototyping starts with getting the requirements of analysis, where the developer has to come up with a broad conceptual solution. A detailed analysis of user's requirements has to be produced. The system design as well as the program design will then be constructed.

Based on the design, the prototype will be developed, then tested and refined. A process of iteration is needed to refine the prototype until all requirements are achieved or until the prototype has evolved into a system suitable to be implemented. During this phase, refining will be done with reference to the requirements of analysis, system and program design.

After confirming the program design, coding for database, user interface, and others will be carried out. Upon completion of this phase, all the units will be integrated into a complete system and tested to ensure that no flaws or bugs exist. Troubleshooting will also be done in this phase. The last phase is the last acceptance test and to maintain the system from time to time.

3.2 Project Schedule

To achieve the objectives of the project in time, a timeline is planned to manage tasks. The schedule will ensure the project is accomplished before the submission date. The project schedule is shown in Table 1.

Contementation	Proj	ect Sc	hedul	e (Jul	y 200	I – Ap	pril 200)2)	and infor	milio

3.3 Requirements Analysis

Implementation of requirement analysis is to discuss more about abstract information and restrictions of the online course registration and payment system. Requirements analysis can be divided into two – functional requirements and non-functional requirements.

3.3.1 Functional Requirements

Functional requirements are the main features that will complete the operation and produce required results of the online course registration and payment system. The lists of functional requirements are as below.

3.3.1.1 Students & Administrators Login Function

This function will allow or restrict students or administrators to access into the following page. Students and administrators need an ID and password to login.

3.3.1.2 Change Password Function

This function allows students and administrators to change their password if they feel the old password is not safe.

3.3.1.3 Payment Calculating Function

This function will assist students to calculate the course registration payment based on the information from the database. The registration fees and examination fees will be automatically summed up. Therefore, the total amount that shown in the calculation would be the total fee that includes registration fee and examination fee.

3.3.1.4 Data Transaction

The modules involved here allow the end users (*UM administrators*) to create, retrieve, delete and update students' information, administrative records and course registration information. This component will ensure the database remains current with the 'real world' and support the information need of the UM administrators.

3.3.1.5 Data Queries

These modules allow UM administrators to retrieve the details of records from the database based on:

- Keywords such as student's matrix number, administrator's ID, and course number.
- ii. Non-keywords such as students and administrators login time.

3.3.2 Non-Functional Requirements

Non-functional modules are the modules that will not affect the system when they are operating and producing the required output. In this system, alteration in administrative records will not affect the required results. For example, a change in administrators' name, ID, and password will not affect the course registration and payment result. Besides that, changing information in the timetable will not affect the required result of the system as well.

3.3.2.1 User Interface

The user interface in the system should present the required information in a userfriendly way. When designing the forms, some useful guidelines need to be followed, including meaningful title, logical grouping and sequencing of fields, visually appealing layout of the forms, familiar field labels, use of distinguished colors, visible space and boundaries for data-entry fields and convenient cursor movement.

3.3.2.2 Storage Capacity

The storage capacity of the database must be enough for the postgraduate students in FSKTM. Besides that, the RAM (Random Access Memory) of the computer must be high enough to support the workload.

43

3.3.2.3 Easy to Use and Understand

A standard navigation buttons and interface design of the system must be used. Furthermore, the information in the system has to be easy to understand.

3.3.2.4 Reliable

The system has to be reliable with less error occurred. The security of the data must be control by User ID and password.

3.3.2.5 Robust

The system has to be robust. Only a little of time need to spend to recover the system when system failure. Data error has to be minimized after system failure with the validation of data if the data are safe to transfer to database.

3.4 Run-Time Requirements

Online Postgraduate Course Registration and Payment System is developed to run on a standalone PC. This standalone PC can act as a server. The operating system for development work is Windows 95/98/2000/ME.

3.4.1 Window 95/98/2000/ME

At least a Pentium II 300 MHz machine

- 64 MB RAM (recommended for performance wise)
- 3.2 GB Hard Disk (recommended for performance wise)
- 52 X CD_ROM Drive
- Modem with at least 56 Kbps
- Other standard computer peripherals

3.5 Data Flow Diagram

Data Flow Diagram (DFD) is a graphical characterization of the data processes and flows in a system. DFD depicts the broadest possible overview of system inputs, processes, and output, which correspond to the data movement through the system. Data flow diagram in this system is shown as below (Figure 3).

i. Context Diagram

Figure 3: Context Level Diagram For An Online Postgraduate Course Registration and Payment System

There are three external entities for this system, namely FSKTM Postgraduate Students UM Bursar's Office, and UM Administrators. These entities are shown in the Context Diagram. The Online Postgraduate Course Registration and Payment System process symbol is a parent process and the details of this process are defined in its child diagram (Diagram 0).

Figure 4: Diagram U For Au Opline Postgraduate Course Registration and Payment Syster

Figure 4: Diagram 0 For An Online Postgraduate Course Registration and Payment System

Figure 5: Diagram 0 (Continue)

These diagrams (Figure 4 & Figure 5) are the more detailed level for Online Postgraduate Course Registration and Payment System. Process and data stores are numbered. There are eleven processes and seven data stores.

4.0 SYSTEM DESIGN

System design is a process through which the requirements are translated into a model or representations of the software that can be assessed for quality before coding begin. For this stage, the requirements that are identified earlier are translated into system features and characteristics.

4.1 Detail Design

4.1.1 Architectural Design

The process model for this architectural design is based on the system structuring and modular decomposition approach.

In system structuring, the system is structured into a number of principal subsystems. A subsystem is a system in its own right, and its operation does not depend on the services provided by other subsystems. Each subsystem is composed of modules, and has defined interfaces, which are needed for communication with other subsystems. (Kendall & Kendall, 1999)

For module decomposition, it is based on assigning functions to components. I begin with a high-level description of the function that are to be implemented and build the lower-level explanations of how each component will be organized and related to other components. (Kendall & Kendall, 1999)

Online Postgraduate Course Registration and Payment System is developed using a modular approach where each module is developed separately in components and are tested thoroughly. By using modular approach, future modifications and enhancements are made easy.

4.1.2 System Architecture

The system architecture of this project consists of two parts, namely data architecture and application architecture. Therefore, the discussion will more concentrate on data structures and system modules in online course registration and payment system.

4.1.2.1 Data Architecture

In this system, there are a few main modules in data architecture that need to be supported.

- □ The functions of view, update, and delete postgraduate students' records.
- □ The functions of view, update, and delete UM administrators' records.
- Course registration and fee payment function.
- The functions of view, update, and delete course record for MIT, MSE, MCS, MLIS, and PHD.

- The function to edit registration fee and examination fee records.
- □ The function of changing students' and administrators' passwords.
- □ Timetables for MIT, MSE, MCS, MLIS, and PHD.
- □ The login functions for students and administrators.
- Generate registration report functions.

4.1.2.2 Application Architecture

Modular decomposition approach was used in designing this system. System functional separates the system into few modules. Modules that involved are:

a) Main page module

The main menu of the application is responsible for allowing the students to select the modules they require. The main menu consist of 4 major hyperlinks; *Home, Course Registration, Time Table* and *Administrator Login.* Besides that, there are three minor links such as FSKTM Site, Postgraduate Enquires Site and Email. This links will bring users to the web page that they would like to visit.

b) Student login module

If a student chooses to enter *Course Registration* module, they have to login with their programme name, ID and password.

c) Student change password module

Students can change their password in this module. The information such as ID number, existing password, and new password are needed for this module to change password.

d) Student's personal information list module

After login, student will go to this module. They can go to their own personal information list like Matrix No, Programme, Full Name, IC No, Sex, Marital Status, Race, Address, Telephone No, and Email. They can update their information such as phone number, home address or email address.

e) Course selections module

Student will then proceed to course selections module to choose the course they want to register for the current semester. In this module, courses name, course code, credit hours, fees per credit hours and fees per course were shown.

f) Course selected module

This module will automatically calculate the course fee including registration fee and examination fee after the student has chosen their course.

g) Fees payment module

This module will allow the student to choose either to pay fees via visa or master card or pay cash to UM Bursar' Office.

h) Timetable module

These are the updated timetables for MIT, MSC, MSE, MLIS and PHD students. All the timetables contain the information such as time for the class start, course name, lecturers' name, and the classroom location.

i) Administrator login module

This module is for the administrators, not students. Administrators like department head, treasurer, lecturer and staff also have to login with ID and password if they want to access this module.

j) Administrator change password module

Administrators can change their password if they feel that the existing password is not safe. The information such as ID number, existing password, and new password are needed for this module to change password.

k) View students' information module

Lecturer and staff only can view the students' records. They cannot edit or delete the students' records. But, the Department Head and UM Treasurer can view, edit, update, and delete the course information, students' records, administrators' records, course registration report, registration fee and examination fee.

l) Edit menu module

This module is only a web page that consists of hyperlinks such as Edit students' information link, Edit administrators' information link, Edit registration fee and exam fee link, Edit MIT course information link, Edit MSE course information link, Edit MCS course information link, Edit MLIS course information link, Edit PHD course information link, Students access list, Administrators access list link, and Course registration reports link.

m) Edit students' information module

Administrators can search, edit, update, add or delete students' record in this module.

n) Edit administrators' information module

Administrators like department head and treasury officer can search, edit, update, add or delete administrators' record in this module.

o) Edit registration fee and exam fee module

Administrators can change the fee's figure every semester.

p) Edit MIT course information module

Administrators can edit, delete and insert the MIT course information.

q) Edit MSE course information module

Administrators can edit, delete and insert the MSE course information.

r) Edit MCS course information module

Administrators can edit, delete and insert the MCS course information.

s) Edit MLIS course information module

Administrators can edit, delete and insert the MLIS course information.

t) Edit PHD course information module

Administrators can edit, delete and insert the PHD course information.

u) Students access list module

Administrators can check students access list if they access this system and register their course. The list will show the login time of all students.

v) Administrators access list module

Administrators can check administrators access list if they access this system. The list will show the login time of all administrators.

w) Course registration reports module

In this module, there is a table that shows all the courses that registered by students. Besides that, administrators can also search the total of students that register a particular course.

4.1.3 Database Design

4.1.3.1 Entity-Relationship (E-R) Model

An E-R model is a logical representation of the data. It illustrates the relationship between entities in the related environment and the attributes of both the entities and their relationship. (Connolly, T. & Begg, 2000). It is commonly used to:

 Translate different view of data among administrators, users and programmers to fit into a common framework.

- Define data processing and constraint requirement to help meeting the different views.
- ✓ Help implement the database.

E-R Diagram for Online Postgraduate Course Registration and Payment System is shown in Figure 6.

Figure 6: E-R Diagram for Online Postgraduate Course Registration and

Payment System

- The relationship between entity TblStudent and entity TblStudentAccess is one to many (1: M). Each student can login many times into the system for course registration and payment.
- ii. The relationship between entity TblStudent and entity TblReg is one to one(1: 1). Each student can register course many times and the records will keep updating every time.
- iii. The relationship between entity TblAdmin and entity TblAccessAdmin is one to many (1: M). Each administrator can login many times into the system for administrator purposes.
- iv. Entity TblRE and entity TblCourse, does not have relationship.

4.1.3.2 Data Dictionary

i. This table contains the UM administrators information.

Field Name	Data Type	Size	Description

Table 8: Administrators' Login Time

4.1.4 User Interface Design

User interface design is based on the Graphical User Interface (GUI) approach. All the design is created using HTML and JavaScript. A good user interface can be designed by following some structured guidelines as follows:

- Planning the overall structures of the application
- ✓ Planning the content of the application
- ✓ Planning the interactive behavior
- ✓ Planning the look and feel of the application

What You See Is What You Get - the interface should not hold any surprise for the user or exhibit strange behavior. There is no point to establishing metaphors and other aids to help support interaction and then removing user confidence in them by implementing them in an inconsistent manner. If an

4.1.4.1 Principles of Interface Design

Interface design is an area in which few rules exist. There are well-established guidelines and principles that can be used to help improve the potential for success when designing an interface. A few of the more common are considered here.

- Direct Manipulation --- the user will feel in more control of an interactive experience if their physical actions result in physical, or apparently physical, results. This is one of the reasons we see features such as moveable icons and interface elements such as sliders on scrollbars.
- Aesthetic Integrity --- confusing and unattractive interfaces only serve to confuse and annoy the user. The interface should be clear and uncluttered.
- Feedback and Dialogue --- users need feedback in order to know what's happening, allowing them to feel comfortable in using the system. We have to make feedback timely, concise and make it understandable to the user.
- What You See Is What You Get --- the interface should not hold any surprise for the user or exhibit strange behavior. There is no point to establishing metaphors and other aids to help support interaction and then removing user confidence in them by implementing them in an inconsistent manner. If an

element requires the inclusion of odd, or magic, properties, then it probably is not appropriate for the use being made of it.

 Frequency of User Versus Accessibility of Functionality --- make frequently used functionality easy to access and place the bits and pieces that are seldom used out of the way, to help simplify the interface. It is also useful to place dangerous functions where they will not be triggered accidentally.

This page consistent a menu that includes Home. Course Registration, Time Table, and Administrator Login. It allows users to select the module they require. Besides that, there are two links that will bring users to FSKTM web site and Postgraduate improve web site. Furthermore, there is an email item at the botton of the page allow torus to send could to the person in charge if they have any quachous regarding the written.

4.1.4.2 Main Page Design

The interface design of the main page is shown below.

Figure 15: Payment Page Design

Here, the students need to select their mode of payment. They can either pay their fees via visa or master card or pay cash to UM Bursar' Office. If they want to pay by visa or master card, they need to complete all the entries like card type, card number, name on card, expiry date of the card, and card holder address, as shown in Figure 15. Then, click "*Submit*" button. All this information will receive by UM Bursar's Office. After that, UM Bursar's Office will contact the bank electronically and verify that credit card information students have provided matches the credit card information that bank has provided to UM Bursar's Office, the course registration will be delayed or canceled.

However, if they want to pay cash to UM Bursar' Office, just click "OK". Then the record will be stored in the database. Students need to settle their fees within two weeks after the course registration.

Figure 18: Administrator Login Page Design

If the administrators would like to change their password, they need to click on the "*Change Password*" button, a page look like the one in Figure 9 will appear. The steps to change password is exactly the same as for the students.

For login into the administrator login page, administrators have to fill in the *Status*, *ID*, *and Password* text box as shown in Figure 18. There are four type of status for administrators: Department Head, Treasurer, Lecturer and Staff. If *Status*, *ID*, *and Password* is not match, then access is denied. If the login is successful, then the page as shown in Figure 19 will appear.

All the students that register course WRGA6302 will be shown in the table.

5.0 SYSTEM TESTING AND IMPLEMENTATION

This phase involves some modifications to the previous design. System testing has been gone through to minimize the programming error and system error. Then, the way to implement the system will be discuss further.

5.1 Testing Strategies

In developing this system, testing involves several stages. First, each program component is tested on its own, isolated from the other components in the system. Such testing is known as *unit testing* or *component testing*. This stage of testing will verify whether the component functions properly with the types of input and output expected from studying the component's design. After each component has been tested, the interaction between these components is tested again to ensure that the components can be integrated. (Dr.P.Sellapan, 2000)

When all components have been unit-tested, the next step is ensuring that the interfaces among the components are defined and handled properly. This step is called *integration testing*, also known as *module testing*, which verifies that the entire component can work together as described in the module or system design specifications.

Finally, system testing is performed to ascertain that the whole system works according to the requirement description and specifications. System modification will be carried out if the requirements as described in the specification are not met.

5.1.1 Unit Testing

Unit testing concentrates on the smallest unit of software design, which is the module. A module is a collection of components, which are independent from each other. After each component unit has been tested, the interaction between these components will be tested. Unit testing is done concurrently with the prototyping phase in the development of this project. For example, "*edit postgraduate student record*" in the record is one of the sub-modules with many sub-functions. The insertion of student particulars and other functions (*delete & update*) are tested to ensure that the module is error free and the records can be saved and retrieved from database correctly. (Kendall & Kendall, 1999)

In the development of this system, unit testing is done after the development of each module and not the end of the whole system development. The object and programming codes are thoroughly checked and tested to ensure that the function and data are implemented properly as indicated in the design. If there were any error, debugging would be carried out to identify the error before testing the unit again.
Other unit that is independently unit-tested such as opening and closing of connection to the database are also important.

5.1.2 Module Testing

The objective of module testing (also known as integration testing) is to take unittested modules and build program structure that encapsulates all of the related modules. This testing will ensure that the module calling sequence in this project is systematic.

In module testing, two or more units in which either unit that use output data from or provide input data for another unit are tested in collection. These units have related characteristics to perform a common goal or function. (Kendall & Kendall, 1999)

All the ASP objects were integrated and tested to ensure the success of integration. Multiple values of test data were entered through the interface to ensure that values were inserted correctly into the database.

5.1.3 System Testing

The last testing procedure is *system testing*. Once all the modules are tested, they are tested in concert to verify that all the elements are functioning and interfacing with each other properly. The testing result will show whether or not the entire system specifications and objectives are achieved. (Kendall & Kendall, 1999)

5.2 System Testing

System testing to the applications that have been developing in the system is to satisfy the scope and the objectives. Modules that involved are:

- Main page module
- Student login module
- Student change password module
- Student's personal information list module
- Course selections module
- Course selected module
- Fees payment module
- o Timetable module
- Administrator login module
- Administrator change password module
- View students' information module
- Edit menu module
- Edit students' information module

Edit administrators' information module
Edit registration fee and exam fee module
Edit MIT course information module
Edit MSE course information module
Edit MCS course information module
Edit MLIS course information module
Edit PHD course information module
Students access list module
Administrators access list module
Course registration reports module

5.2.1 Main page module testing

Testing on the link function of each hyperlinks to make sure the navigations are correct.

5.2.2 Student login module testing

In this module, enter the correct and false student's programme, ID and password to check whether can access to the next page. Then, the functionality of the buttons also been checked. The error message box will prompt out if the user makes an error.

5.2.3 Student change password module testing

In this module, the correct student's programme, ID, existing password and new password have been entered to make sure the password is successfully changed. The system will prompt out the words " Password Successfully Changed " if the existing password has been changed.

5.2.4 Student's personal information list module testing

Enter the new data in this module and make sure all the data can be updateable. Error message box will prompt out if user makes an error.

5.2.5 Course selections module testing

This module is tested by select the same courses, and then, no course is selected. The error message box will prompt out and show users the error they have made.

5.2.6 Course selected module testing

Check whether the course name and course code are the same as the one that have been selected. Then, check whether the total of course fees, credit hours and fees per credit hours are correct.

5.2.7 Fees payment module testing

In this module, try to enter the false information in the text box to see whether the error message box will prompt out. If all the information that entered is correct, then the system will store all the information in the database. The system will tell the users that they have successfully done the registration.

5.2.8 Timetable module testing

Testing on the links to every timetable to make sure all the links will go to the correct timetables.

5.2.9 Administrator login module testing

In this module, enter the correct and false administrator's status, ID and password to check whether can access to the next page. Then, the functionality of the buttons also been checked.

5.2.10 Administrator change password module testing

In this module, the correct administrator's status, ID, existing password and new password have been entered to make sure the password is successfully changed.

5.2.11 View students' information module testing

The correct and false students' matrix number have been entered to test whether the system is showing the correct students record.

5.2.12 Edit menu module testing

Testing on the link function of each hyperlinks to make sure the navigations are correct.

5.2.13 Edit students' information module testing

In this module, make sure the particular student's record can be updated and deleted. Besides that, make sure add the new student function is workable. The new student's record must be store in the database. Retrieve the information (new student record) back after the adding process to check whether the new record is correct. Make sure the correct error message box prompt out when make mistake.

5.2.14 Edit administrators' information module testing

In this module, make sure the particular administrator's record can be updated, deleted and added. Make sure the correct error message box prompt out when make mistake.

104

5.2.15 Edit registration fee and exam fee module testing

Enter the different figures of registration fee and exam fee in the text boxes and update the information. Then check in the course-selected module whether the figure of registration fee and exam fee are the same.

5.2.16 Edit MIT course information module testing

In this module, check the courses can be edited, updated, deleted and added. Make sure the correct error message box prompt out when make mistake.

5.2.17 Edit MSE course information module testing

In this module, check the courses can be edited, updated, deleted and added. Make sure the correct error message box prompt out when make mistake.

5.2.18 Edit MCS course information module testing

In this module, check the courses can be edited, updated, deleted and added. Make sure the correct error message box prompt out when make mistake.

5.2.19 Edit MLIS course information module testing

In this module, check the courses can be edited, updated, deleted and added. Make sure the correct error message box prompt out when make mistake.

5.2.20 Edit PHD course information module testing

In this module, check the courses can be edited, updated, deleted and added. Make sure the correct error message box prompt out when make mistake.

5.2.21 Students access list module

In this module, check whether the access time to the system is correct. Then, test the delete record function is workable.

5.2.22 Administrators access list module

In this module, check whether the access time to the system is correct. Then, test the delete record function is workable.

5.2.23 Course registration reports module

In this module, the link functions of every hyperlink are tested. Make sure the link functions will link to the correct pages. Then, the workable of the search function in the module has been tested. Enter the course code and then check whether the correct students are registering that particular course.

5.3 System Implementation

System implementation is a process that converts the system requirements and designs into program codes. Online Postgraduate Course Registration and Payment System is developed using the top-down approach which involves building the high-level system modules which are further refined into function and procedures. Therefore, this system can be implemented by a few module and sub module.

Figure 37: Online Postgraduate Course Registration and Payment System Main

Page

The main page shows a menu that contains 4 main functions that can be chosen.

- Home This function allows the students to return to the main page of the
 Online Postgraduate Course Registration and Payment System.
- ii. Course Registration This function allows the students to register for the courses they want to study for a particular semester. Students can also update their personal details. After registration, students can pay their fees online.

- iii. Time Table This function allows the students to view the latest timetable for the semester.
- iv. Administrator Login This function can only be accessed by administrators such as head of the department, UM Treasury, lecturer and staff of the department to view, delete or edit students personal details and course registration information.

Besides the 4 main functions, there are 3 small functions at the bottom of the main page.

- FSKTM Site Students can get more information about Faculty of Computer Science and Information Technology.
- Postgraduate Enquires Site Students can get more information about their program in this site.
- iii. Email Icon Students can email to that email account if they have any questions.

5.3.2 Course Registration

To start the course registration, click on the word "*Course Registration*" at the menu. The following page will appear.

Figure 39: Change Password

Fill in the information in the text box and click on "Submit" button.
 Try using the ID and password below. Then, try to create own new password.

ID = wgd00030 and Password = 123 or

ID = wgd00031 and Password = 123

If all the information entered is correct, then a "Password Successfully Changed " page will appear next.

Figure 40: Password Successfully Changed

- iv. Then click on the word " Click here " to login again with the new password.
- v. If information entered in the text is not complete, the password that entered in the text box does not match with the ID or the two new passwords in the text box are not the same, then have to try again.

5.3.2.2 Student Login

i. User have to login with your ID and password as shows in Figure 41. For example,

Programme = Master of Information Technology

ID = wgd00030 Password = 123

Or

Programme = Master of Software Engineering

ID = wgd00031

Password = 123

Or

Programme = Master of Computer Science

ID = wgd00035

Password = 123

Figure 69: Students that Register Course WRGA6302

All the students who registered for course WRGA6302 will appear in the table.

6.0 SYSTEM EVALUATIONS AND CONCLUSIONS

6.1 Strengths

6.1.1 Simple and Easy to Maintain

Due to the simplicity of the web application development, it can be maintained by anyone with minimal experience in using Active Server Pages and Microsoft Access (databases). This is especially important for a company that has no prior experience in managing a DBMS and fresh programmers.

6.1.2 Low Cost of Ownership

The system is easy to deploy, manage and upgrade as technology evolves. This is achieved through application level programming interface that supports various development needs. Microsoft Access 2000 was choosing to be the database of this project because the cost is reasonable and easy to use. It is suitable for developing the small and medium system.

6.1.3 High Level of Upgrade

The system can be easily upgraded. The database initially created using Microsoft Access 2000 can be migrated to the Microsoft SQL Server 7.0 easily using the Access Upsizing Wizard.

6.1.4 Navigation of the System

Users can navigate the system easily. This is because the navigation buttons and icons in the system are user friendly and easy to understand.

6.2 Limitations

6.2.1 Stability

The system maybe unstable once we upload it onto the web. Usually, the stability of the system is affected by the stability of the database. Therefore, Microsoft SQL Server 2000 or DB2 is encouraged to use for system database. It is because there are more stable.

6.2.2 Low Recoverability of Stored Data

Due to the integrated nature of the Microsoft databases files (.mdb), if the database file is corrupted, it is usually difficult to recover the stored data.

6.2.3 Manual Backup of Database

There is no automatic backup mechanism for the .mdb file and backup would have to be done manually.

6.2.4 Storage Capability

Microsoft Access has a limit on the amount of data that can be stored in the database. Once the records exceeded a certain quantity, new records cannot be store anymore. The capability will be low when the workloads increase.

6.2.5 Interface Design

Interface designs in this system are not attractive and static. But, the major purpose of application development of this system is to make the system more users friendly. Therefore, the animation factor has been neglected.

6.2.6 Security

Even though the system only can be accessed using User ID and Password, but the security of the data transactions and steps to prevent system hacking have been neglected. This is because the lack of securities software and equipments and the duration of developing this system is short.

6.3 Future Enhancements to Upgrade the Quality of the System

The applications of the system are prototype that can be upgraded to the new functions and securities features as below:

6.3.1 Security Features

Online security is a major concern for those who are contemplating online payment. This is likely due to the high profile website hackings and online security breaches that occasionally make the news headlines.

If an organization really wants to use this system, I suggest that they have to deal with the service provider regarding the security features in the web site. Most service providers will try to allay our fears by explaining the measures they take to protect transactions.

All Internet service providers use Secure Socket Layer (SSL) technology, which encrypts (scrambles) data so only certain people can read it. Some providers also use Secure Electronic Transaction (SET) technology as an added security measure.

A secure connection is very important whenever for any transaction online. Depending on what the browser that is use, either a closed padlock icon (Internet Explorer) or a key icon (Netscape Navigator) at the bottom of the web page.

This indicates that the transaction is being encrypted, and the users should not worry about someone else eavesdropping on his account. Besides that, the Internet service provider should be using high-end encryption. For example, 128-bit encryption. To check this out, refer to the text next to the padlock or key icon. It should be "RC4-128". (Kalakota, Ravi & Whinston A, 1996)

Nevertheless, evaluating the security of the website is beyond the scope of this project.

6.3.2 Designing and Deploying Web-Enabled Applications: A Changing Architecture for Changing Needs

With many forces influencing how the Internet behaves and operates, utilizing global network in the same way as it is used in private network presents many challenges. To transform the global network into a reliable application platform, the original architecture of the web must be enhanced to meet the needs that were taken for granted when developing traditional applications. The enhanced architecture to develop and deploy the Web-enabled applications can be seen in Figure 70. (Poo Kuan Hoong, 2000)

Figure 70: The evolution of Web architecture to support the basic needs of a Web-enabled application

The Web-based architecture represents a shift back to the server-centric deployment model. This model enables a centralized deployment and distribution mechanism without relying on individual client configurations. Furthermore, the server-centric model also enables a central connection point to external resources, such as in-house data stores like Microsoft Exchange, Lotus Notes, or own custom-built proprietary data systems.

6.3.3 Good Quality of Performance Database Server

The database that has been used in the system is Microsoft Access 2000. It is advisable to use a good quality of performance database such as SQL Server or Oracle that has good security features.

6.3.4 Stable Web Server

Microsoft 2000 Server can be used as a web server because it has the good security features and stable if compare with Microsoft Window 98.

6.3.5 Implement Firewall

Implementation of firewall can avoid the system hacking and viruses attack to the system. The leak of information after system hacking will affect the reliability of the system from the users. The lost of data after virus attack is a cost to the UM administrators as well as the students.

6.3.6 Cisco

Cisco is good because it contents switching solutions ensuring secure and fast online course registration. Cisco 11000 Series Content Services Switch (CSS) and the Cisco 11000 Series Secure Content Accelerator (SCA) can enhance the performance of online course registration application, guaranteeing 100 percent server availability and ensuring secure and successful online registration.

Cisco provides a hardware/firmware solution that is able to handle a higher volume of users. The Cisco CSS 11000 Series also provides automatic fail over between servers for increased availability as well as denial-of-service protection for increased security. The flexibility and simplicity in configuring the hardware are the advantages of using Cisco.

6.4 Conclusion

E-commerce is a fast moving area internationally in terms of opportunities and technologies. It is predominantly leads by industry and user sector with Government playing a catalytic role providing pro-active and facilitating support and critical inputs for growth.

In addition, the Internet is radically changing the way consumers shop for goods and services. Credit providers, and especially retailers, are more than willing to satisfy their appetite to buy whatever they need, whenever they need it, without leaving the comfort of office or home. Unfortunately, the Internet is also opening up fresh vistas for a new generation of technologically savvy criminals to steal with greater anonymity, and sending creditors and merchants scrambling to find new products and technologies to protect themselves — and their customers — from fraud. Therefore, to help combat crime in cyberspace, the credit fraud prevention industries have to provide a number of new products and marketing those tools to credit and retail businesses.

Finally, I wish the objectives of this project can be achieved and the system will greatly improve the operational performance in course registration and fees payment by postgraduate students and operational performance of the related tasks by UM administrators. The use of this system could be also expanded to whole UM students.

GLOSSARY

Data Flow Diagram (DFD)

A type of graphical representation of flows and data processes in a system. In their original state DFD depicts the broadest possible overview of the system's inputs, processes, and output, in which correspond to data movement in the system.

Entity-Relationship Model

A detailed logical representation of entities, attributes, and relationship for a company.

Open Database Connectivity (ODBC)

A standard protocol for database servers. If a database has an ODBC driver which is used to connect to ODBC-compliant data sources.

ActiveX Data Objects (ADO)

A set of ActiveX components designed to access ODBC data.

OLEDB

A specification that defines a set of standard interfaces for accessing data. The ActiveX

Data Objects (ADO) implement the OLEDB standard.

Data Definition Language (DDL)

Used by the DBMS to physically establish record types, fields, and structural relationships. Additionally, the DDL defines views of the database. Views restrict the portion of a database that may be used or accessed by different users and programs. DDLs record the definitions in a permanent data repository.

Data Manipulation Language (DML)

Used to create, read, update and delete records in the database and to navigate between different records and types of records----for example, from a customer record to the order records for that customer. The DBMS and DML hide the details concerning how records are organized and allocate to the disk.
