Abstract

The Asian Arowana (*Scleropages formosus*) is a primitive freshwater fish from the Jurassic era. It is very hardy and can live a good half century. Its low fecundity rate (about 30 eggs per batch), coupled with habitat degradation, threaten the future survivability of this fish (Khan *et al.*, 1996). It was once close to extinction. In this study, microsatellites were used to study the allele frequencies, heterozygosity as well as the genetic differences among varieties.

To identify microsatellite loci without the expense of library screening, a new strategy has been proposed by Fisher *et al.* (1996). This approach, called the 5' anchored PCR, employs a primer containing microsatellite repeats followed by a degenerated anchor at its 5' end. The amplification produces two close and inverted microsatellites and the region between them. This microsatellite rich PCR profile is cloned to yield a genomic library enriched for microsatellites. Using this method, twenty pairs of primers were designed, out of which only eight turned out to be polymorphic.

These eight polymorphic loci were screened in *Scleropages formosus* from a sample composed of 88 individuals from 5 different populations. Genomic DNA used for PCR was isolated from the scales of the fish using a high concentration urea buffer (Asahida, 1996). The allele numbers ranged from 1 to 5 per locus.

Statistical analysis shows that most of differentiation observed probably resulted from the poor breeding regime employed and bears no relationship to real divergence. It also shows that this species is compromised and extensive efforts have to be initiated to avoid short term potential for extinction.

Prof SG Tan and fellow students in UPM &
Mom for her encouragement.

Table of Contents

	page
Chapter 1 – Introduction	
1.1 The Arowana	1
1.1.1 Description	1
1.1.2 Geographic distribution	2
1.1.3 Breeding	5
1.1.4 Trade of the Dragon fish	6
1.1.5 Conservation of the Dragon fish	8
1.2 Previous molecular studies on the arowana genome	9
1.3 Microsatellites	11
1.4 Randomly Amplified Microsatellites (RAMS)	14
1.5 Mutational model	16
1.6 Objective of this study	19
Chapter 2 – Materials	
2.1 Chemicals	20
2.2 Kits	23
2.2.1 BST TECH LAB, PURE-GENE™ PLASMID MINIPREP KIT	23
2.2.2 PROMEGA SILVER SEQUENCE™ DNA STAINING REAGENTS	24
2.2.3 INVITROGEN, TOPO TA CLONING KIT	24
Chapter 3 – Experimental Procedures	
3.1 Sample collection	25
3.2 Genomic DNA Extraction	26
3.3 Preparation of Luria-Bertani (LB) Plates	27
3.4 Cloning	27
3.4.1 PCR amplification	28
3.4.2 Setting up TOPO® Cloning Reaction	29
3.4.3 Transformation of TOPO® Cloning Reaction into One Shot® Chemically competent cells	29
3.4.4 Selection of White or Light Blue Colonies	30
3.5 Preparation for Hybridization	30
3.5.1 Transferring colonies to Nitrocellulose filter	30
3.5.2 Lysis of colonies and Binding of DNA to Nitrocellulose Filter	31
3.5.3 Pre-hybridization	31
3.5.4 3'-End labelling of oligonucleotide with terminal deoxynucleotidyl transferase recombinant (rTdT)	32
3.5.5 Hybridization	33
3.6 Inoculation of Bacteria in LB Broth	33

3.7	Miniprep Plasmid Extraction	34
3.8	DNA sequencing	35
3.9	Primer designing	36
3.10	Primer synthesis	36
3.11	PCR amplification for microsatellite	36
3.12	Acrylamide gel electrophoresis	37
3.13	Silver Staining	38
3.14	Statistical analysis	39
	3.14.1 Allele frequency	39
	3.14.2 Rho statistics	39
	3.14.3 Dendogram	40
Chapter 4 – Results and Discussion		
4.1	Genomic DNA Isolation	41
	4.1.1 Fish samples	42
4.2	Degenerate primer design and PCR testing	44
4.3	Cloning	45
4.4	Colony hybridization	46
4.5	Plasmid Minipreps Extraction	47
4.6	DNA sequencing	48
4.7	Primer design	52
4.8	Amplification of microsatellites using PCR	58
4.9	Statistical analysis	59
	4.9.1 Allele frequency	59
	4.9.2 Population differentiation, Rst	62
Conclusion		64
