ABSTRACT

Introduction: The success of a well-fitting and anatomically correct maxillofacial prosthesis is compromised if the colour does not match the adjoining tissues.

Objectives: The purpose of this study was to examine the ability of the spectrophotometer, digital camera and scanner in reproducing skin colour and to create a system of classifying skin colour in a sample of the Malaysian population.

Materials and methods: Two image capturing devices (digital camera and flat-bed scanner) and a colour measuring device (spectrophotometer) were used to characterize the shade of the forehead in 90 adults from 3 ethnic groups in Malaysia – Malays, Chinese and Indians. Their ages ranged from 20-57 years. Readings from the digital camera and scanner were compared to the readings from the spectrophotometer using CIELAB measurements. The skin shade of each subject captured by each of the 3 devices was then printed on matt photographic paper. 4 observers with normal colour vision were allowed 1-2 minutes to match the printed skin shade to the actual shade of each subject's forehead. They were asked to rate each of the printed colour matches as good, acceptable or poor. Data were analysed using descriptive analysis, independent t-test and Chi square test.

Results: The digital camera was assessed to obtain good colour matches in 71.1% of the coloured prints assessed. The digital scanner produced acceptable colour matches in 66.7% of the prints assessed, while 84.4% of the spectrophotometer reproductions were rated as poor. In addition, L*a*b values were different among the three ethnic groups and between gender. The Indian ethnic group had significantly lower L* values (darker shade of skin) than the Chinese who had the highest L* values ($P < .05$) and males had significantly lower L* values than females ($P < .05$). Four shades of skin colour were differentiated among the subjects.

Conclusions: Visual assessment showed that the digital camera reproduction of the skin colour was the closest to the skin shade. The skin shade of the sample of Malaysian population studied may be grouped into dark, medium, fair and light.

Declaration

I certify that this research is based on my own independent work, except where acknowledged in the text or by reference. No part of this work has been submitted for any degree or diploma to this or any other university.

Dr. Humam Laith Mahmood

Acknowledgements

All Praise to ALLAH the Almighty, for giving me the chance, the will, strength and endurance to complete this study.

I would like to express my sincere thanks to my supervisor Assoc. Prof. Dr. Zakiah Mohd Isa for her enthusiasm, guidance and encouragement through the preparation of this dissertation.

Special thanks to Associate Professor Dr Laith M Abdulhadi for his unlimited scientific and technical support regarding the development and continuous amelioration of the research methodology and during my recruitment as a research assistant for skin colour project.

I would also like to acknowledge the assistance of Ahmad Laith Mahmoud for analysing and classifying the skin shades of subjects in the study.

I could not have finished this work without the tremendous support of my beloved parents.

This research was supported by University of Malaya Postgraduate research fund No: IPPP/UPGP/Geran (RU/PPP)PS082/2009C and PJP grant No.FS177/2008C.
