ABSTRACT

In order to evaluate the change in the drug binding ability of human serum albumin (HSA) with the alteration in its native conformation, effect of urea was investigated on the tertiary structure of HSA as well as on its interaction with warfarin, an anticoagulant drug, using fluorescence spectroscopy. Such studies are important from the physiological point of view as alteration in the drug binding capacity of HSA has been noted in several diseases. Both intrinsic fluorescence and tryptophan (Trp) fluorescence were used to monitor these urea-induced changes upon excitation at 280 and 295nm respectively. Fluorescence spectra of native HSA were characterized by the presence of an emission maximum around 339 and 343nm when excited at 280 and 295nm respectively. Incubation of protein with increasing urea concentrations for 12 hours produced a significant decrease in the fluorescence intensity and an initial small blue shift followed by a marked red shift in the emission maximum. In addition to these characteristics, peak splitting was also observed at higher urea concentrations upon excitation at 280nm, which was absent upon excitation at 295nm. Reducing the incubation time with urea from 12 hours to 60 minutes did not significantly affect these characteristics. Urea transition curve showed a two-step, three-state transition with accumulation of an intermediate around 5.2–5.6M urea upon excitation at 280nm against a single-step, two-state transition when monitored by Trp fluorescence, upon excitation at 295nm. Both decrease in the fluorescence intensity and the red shift in the emission maximum were suggestive of unfolding of the protein's tertiary structure at higher urea concentrations.

In warfarin binding experiments, both decrease in the fluorescence intensity and red shift in the emission maximum of HSA fluorescence spectra with increasing warfarin concentrations were suggestive of warfarin binding to HSA. These effects were more pronounced at lower drug concentrations (0–5 μ M) and sloped off at higher drug concentrations (10–40 μ M). Presence of urea in the incubation mixture affected both these signals in a proportionate manner, by showing lesser changes at higher urea concentrations. In other words, loss in drug binding to HSA was observed with increasing urea concentrations, being maximum loss at the highest urea concentration. These results were analyzed with the help of Stern-Volmer equation (Eftink and Ghiron, 1982) and Scatchard equation (Min *et al.*, 2004) to determine the quenching constant (K_{sv}) and apparent binding constant (K_b), respectively. Whereas decrease in the value of quenching constant with increasing urea concentrations suggested the increase in the distance between excited fluorophore (Trp-214) of HSA and the ligand (warfarin), loss in drug binding ability was reflected by the decrease in the binding constant in the presence of urea. Taken together, all these results suggested significant alteration in the three-dimensional structure of the protein at higher urea concentrations which affected its warfarin binding ability to a significant extent.

ABSTRAK

Dalam usaha untuk menilai perubahan dalam kemampuan pengikatan ubat pada albumin manusia serum (HSA) dengan perubahan dalam konformasi asli, kesan urea telah diselidiki pada struktur tertier HSA serta tindak balas dengan warfarin, ubat antikoagulan, menggunakan spektroskopi pendarfluor. Kajian sedemikian adalah penting dari sudut pandangan fisiologi sebagai perubahan dalam kapasiti pengikatan ubat pada HSA telah dicatatkan dalam beberapa penyakit. Kedua-dua intrinsik pendarfluor dan tryptophan (TRP) pendarfluor digunakan untuk memonitor perubahan-perubahan ini yang diaruhkan oleh urea ke atas pengujian masing-masing pada 280 dan 295nm. Spektrum pendarfluor HSA asli yang dicirikan oleh kehadiran emisi maksimum sekitar 339 dan 343nm apabila diujakan masing-masing pada 280 dan 295nm. Pengeraman protein dengan meningkatkan kepekatan urea selama 12 jam telah menghasilkan penurunan yang ketara dalam keamatan pendarfluor dan permulaan kecil anjakan biru (blue shift) diikuti dengan anjakan merah (red shift) yang jelas dalam emisi maksimum. Tambahan pada ciri-ciri ini, belahan puncak juga dilihat pada kepekatan urea yang lebih tinggi apabila pengujian pada 280nm, yang tidak hadir apabila pengujian pada 295nm. Pengurangan masa pengeraman dengan urea dari 12 jam hingga 60 minit tidak memberi kesan yang ketara kepada ciri-ciri ini. Lengkung transisi urea menunjukkan satu dua-langkah, transisi tiga-keadaan dengan pengumpulan satu keadaan antara pada kepekatan urea 5.2-5.6M apabila diujakan pada 280nm berlawanan terhadap transisi satu langkah, dua transisi dua-keadaan apabila dimonitor oleh TRP pendarfluor, apabila pengujian pada 295nm. Kedua-

dua pengurangan dalam keamatan pendarfluor dan anjakan merah (red shift) dalam emisi maksimum mensarankan berlakunya pembukaan (unfolding) struktur tertier protein pada kepekatan urea yang lebih tinggi.

Dalam uji kaji pengikatan warfarin, kedua-dua pengurangan dalam keamatan pendarfluor dan anjakan merah (red shift) dalam emisi maksimum spektrum pendarfluor HSA dengan peningkatan kepekatan warfarin mensarankan warfarin mengikat kepada HSA. Kesan ini adalah lebih ketara pada kepekatan ubat yang lebih rendah (0-5 μ M) dan menyelinap pergi pada kepekatan ubat yang lebih tinggi (10-40 μ M). Kehadiran urea di dalam campuran pengeraman memberi kesan kepada kedua-dua isyarat ini dengan cara yang seimbang, dengan menunjukkan perubahan yang kurang pada kepekatan urea yang lebih tinggi. Dalam erti kata lain, kehilangan dalam pengikatan ubat pada HSA telah diperhatikan dengan kepekatan urea yang semakin meningkat, dengan kerugian yang maksimum pada kepekatan urea tertinggi. Keputusan ini telah dianalisis dengan bantuan persamaan Stern-Volmer (Eftink dan Ghiron, 1982) dan persamaan Scatchard (Min et al, 2004) untuk menentukan 'quenching constant' (K_{sv}) dan apparent binding constant (K_b), masing-masing. Manakala pengurangan dalam 'quenching constant' dengan peningkatan kepekatan urea mencadangkan peningkatan dalam jarak antara keterujaan fluorophore (TRP-214) HSA dan ligan (warfarin), kehilangan keupayaan pengikatan ubat dicerminkan oleh penurunan 'binding constant' dengan kehadiran urea. Diambil bersama-sama, semua keputusan ini mencadangkan perubahan ketara dalam struktur tiga dimensi protein pada

kepekatan urea yang lebih tinggi yang memberi kesan kepada keupayaan mengikat warfarin yang agak signifikan.

ACKNOWLEDGEMENTS

I would like to extremely thank my supervisor, **Professor Dr. Saad Tayyab**, who has guided, supported, and encouraged me as I wrote this dissertation. During my master study, he gave me many opportunities to develop my academic insights and practical experiences.

I am also grateful to my lab mate, Adyani Azizah Bt. Abd. Halim for her help, patience, and support throughout the project.

I thank my parents and my sister for their personal supports, sacrifices and encouragement throughout the whole project.

I especially appreciate my husband Ebrahim for the countless days he provided me with free time to study and write and whose supportive and loving nature kept me going.

Finally, I also thank my other family members and friends who supported me and tolerated my absence at many events.

(NASIM SAKHAEI)
