

CHAPTER 4

RESULTS

4.1 Yield of Crude Extracts

Forty species of vegetables were extracted using two solvents systems namely, methanol and water. The yield of extracts obtained from methanol and water extraction are shown in Table 4.1.

The total yield percentages range from 5.72% to 48.78%. The *Lycopersicum esculentum* showed the highest total yield percentage while *Centella asiatica* showed the lowest. Generally, the yield percentages of the crude methanol extracts (ranged 1.74% to 37.44%) were higher than that of the water extracts (ranged 2.01% to 27.90%).

Table 4.1 Yield of crude extracts obtained from selected vegetable species

No	Plant	Extraction Solvent	Weight (g)	Yield (%)	Total yield (%)
1	<i>Asparagus officinalis</i>	Methanol	3.23	6.16	15.26
		Water	3.82	9.10	
2	<i>Allium fistulosum</i>	Methanol	2.71	13.58	28.66
		Water	3.01	15.08

4.2 Screening For The *In vitro* Cytotoxic Activity of Crude Methanol and Water Extracts of Selected Vegetables

In the present study, 80 crude methanol and water vegetable extracts were evaluated for their *in vitro* cytotoxic activity against two cervical cancer-derived cell lines (HeLa and CaSki) and human fibroblast cell line (MRC5) using the neutral red cytotoxic assay. HeLa and CaSki cells were grown in 10% supplemented RPMI 1640 medium and MRC5 cells grown in 10% supplemented EMEM medium were incubated with methanol and water extracts of selected vegetables at varying concentrations (1, 10, 25, 50, 100 $\mu\text{g/ml}$) for 72 hours in a 5% CO_2 incubator at 37°C. The negative controls consisted of cells not treated with vegetable extracts. Figure 4.1 shows human cancer cell lines, HeLa, CaSki and MRC5 cells treated with 100 $\mu\text{g/ml}$ of vegetables crude extracts. The negative controls exhibited normal proliferation rate and showed no sign of death after the incubation time of 72 hours, while HeLa, CaSki and MRC5 cells treated with 100 $\mu\text{g/ml}$ of vegetables crude extracts exhibited decrease in proliferation rate and showed signs of death after the incubation period of 72 hours.

The cytotoxicity results obtained were presented as inhibition percentages relative to the negative control and the IC_{50} values were extrapolated from the dose response curves plotted from the percentage of inhibition values. The IC_{50} value is the concentration of extract that inhibits the growth 50% of cells. An extract which gives IC_{50} value of 20 $\mu\text{g/ml}$ and below is considered cytotoxically active (Geran *et al.*, 1972; Chiang *et al.*, 2003).

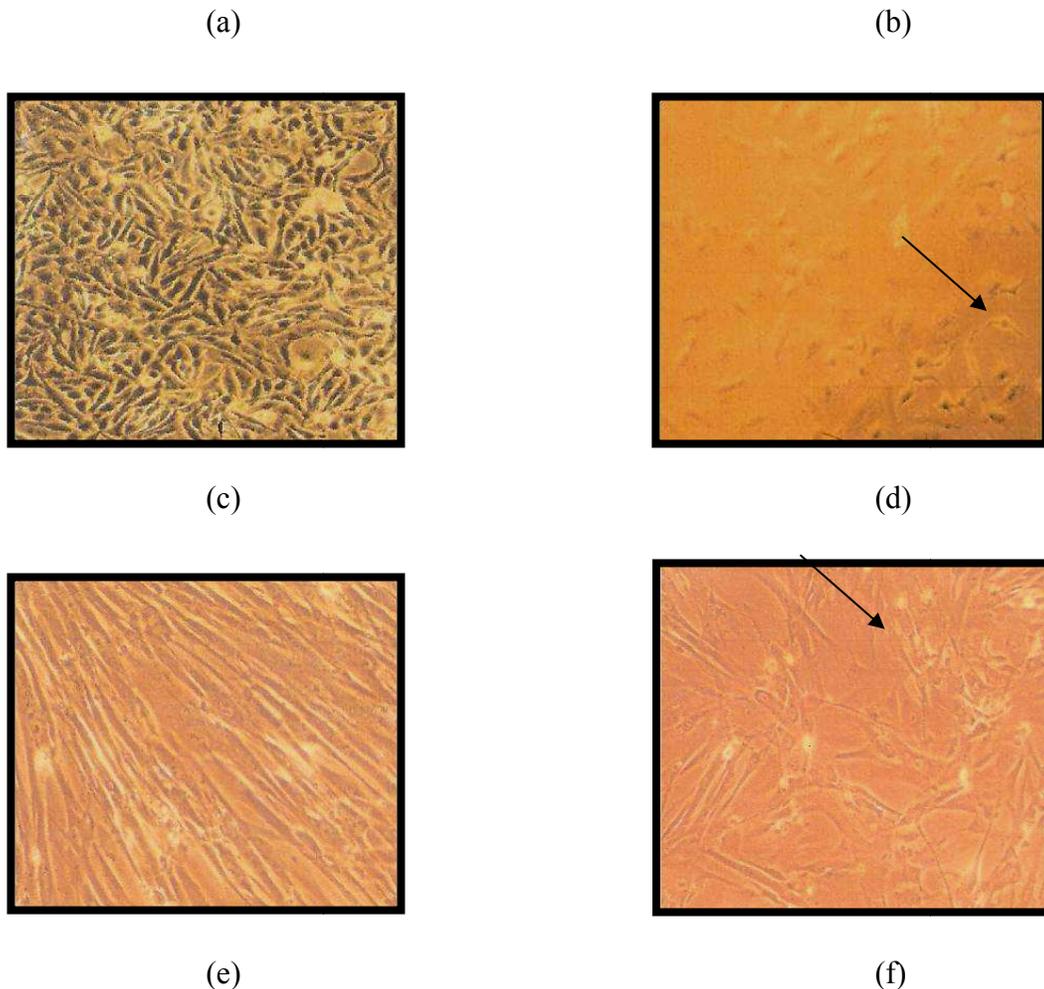

Figure 4.1: Photomicrograph (100X) of: (a): Untreated CaSki cells incubated (negative control) (b): CaSki cell treated with 100 µg/ml of crude extract of *Beta vulgaris* (c): untreated HeLa cells incubated (negative control) (d) CaSki cell treated with 100 µg/ml of crude extract of *Portulaca oleracea* (e): untreated MRC5 cells incubated in EMEM (Negative control) (f): MRC5 cells treated with 100 µg/ml of crude MeOH extract of *Capsicum annum*

4.2.1 Cytotoxic Activity of Doxorubicin Against HeLa and CaSki Cells and MRC5

Cell Lines

The human cervical cancer-derived cell lines, (HeLa and CaSki) and human fibroblast cell line (MRC5), were treated with doxorubicin, a positive control for the neutral red cytotoxic assay.

Cells treated with doxorubicin exhibited decreased proliferation rate and showed signs of death after the incubation of 72 hours. Results showed that the doxorubicin shown significant cytotoxic effects against HeLa, CaSki and MRC5 cells (Table 4.2, Table 4.3, Figure 4.2). Doxorubicin to be cytotoxic of all cell lines tested in a dose-dependent manner with inhibition percentages of 5.89-44.99% at 1×10^{-5} $\mu\text{g/ml}$, 13.08-45.46% at 1×10^{-4} $\mu\text{g/ml}$, 23.86-47.68% at 1×10^{-3} $\mu\text{g/ml}$, 46.81-69.91% at 1×10^{-2} $\mu\text{g/ml}$, 46.95-76.36% at 1×10^{-1} $\mu\text{g/ml}$, 50.91-84.54% at 1×10 $\mu\text{g/ml}$, 53.10-87.82% at 1×10^1 $\mu\text{g/ml}$ and 63.39-89.48% at 1×10^2 $\mu\text{g/ml}$.

The inhibition percentages obtained were presented as dose-respone curves. The *in vitro* growth inhibition of doxorubicin against HeLa, CaSki and MRC5 cell lines are shown in Figure 4.2. The IC_{50} values were estimated from the graph extrapolation and summarized in Table 4.3. The IC_{50} value refers to the effective dose (concentration of extracts in $\mu\text{g/ml}$) that inhibits 50% of cells growth. Extracts having an IC_{50} value equal to or less than 20 are considered active for cytotoxic assay against cells (Geran *et al.*, 1972).

Table 4.2: Inhibition of HeLa, CaSki and MRC5 cells treated with doxorubicin

Cell line	Percentage of inhibition \pm standard deviation (%) at different concentration ($\mu\text{g/ml}$)							
	1×10^{-5}	1×10^{-4}	1×10^{-3}	1×10^{-2}	1×10^{-1}	1	10	100
HeLa	20.1 \pm 5.5	21.6 \pm 9.4	26.5 \pm 1.7	46.8 \pm 2.8	47.0 \pm 0.9	53.6 \pm 0.5	55.3 \pm 0.7	63.3 \pm 1.3
CaSki	5.9 \pm 3.7	13.1 \pm 1.3	23.9 \pm 0.5	69.9 \pm 1.5	76.4 \pm 0.5	84.5 \pm 0.2	87.8 \pm 0.4	89.5 \pm 0.4
MRC5	45.0 \pm 0.12	45.5 \pm 0.6	47.7 \pm 0.4	48.3 \pm 0.3	49.0 \pm 0.5	50.9 \pm 0.5	53.1 \pm 0.4	68.4 \pm 1.4

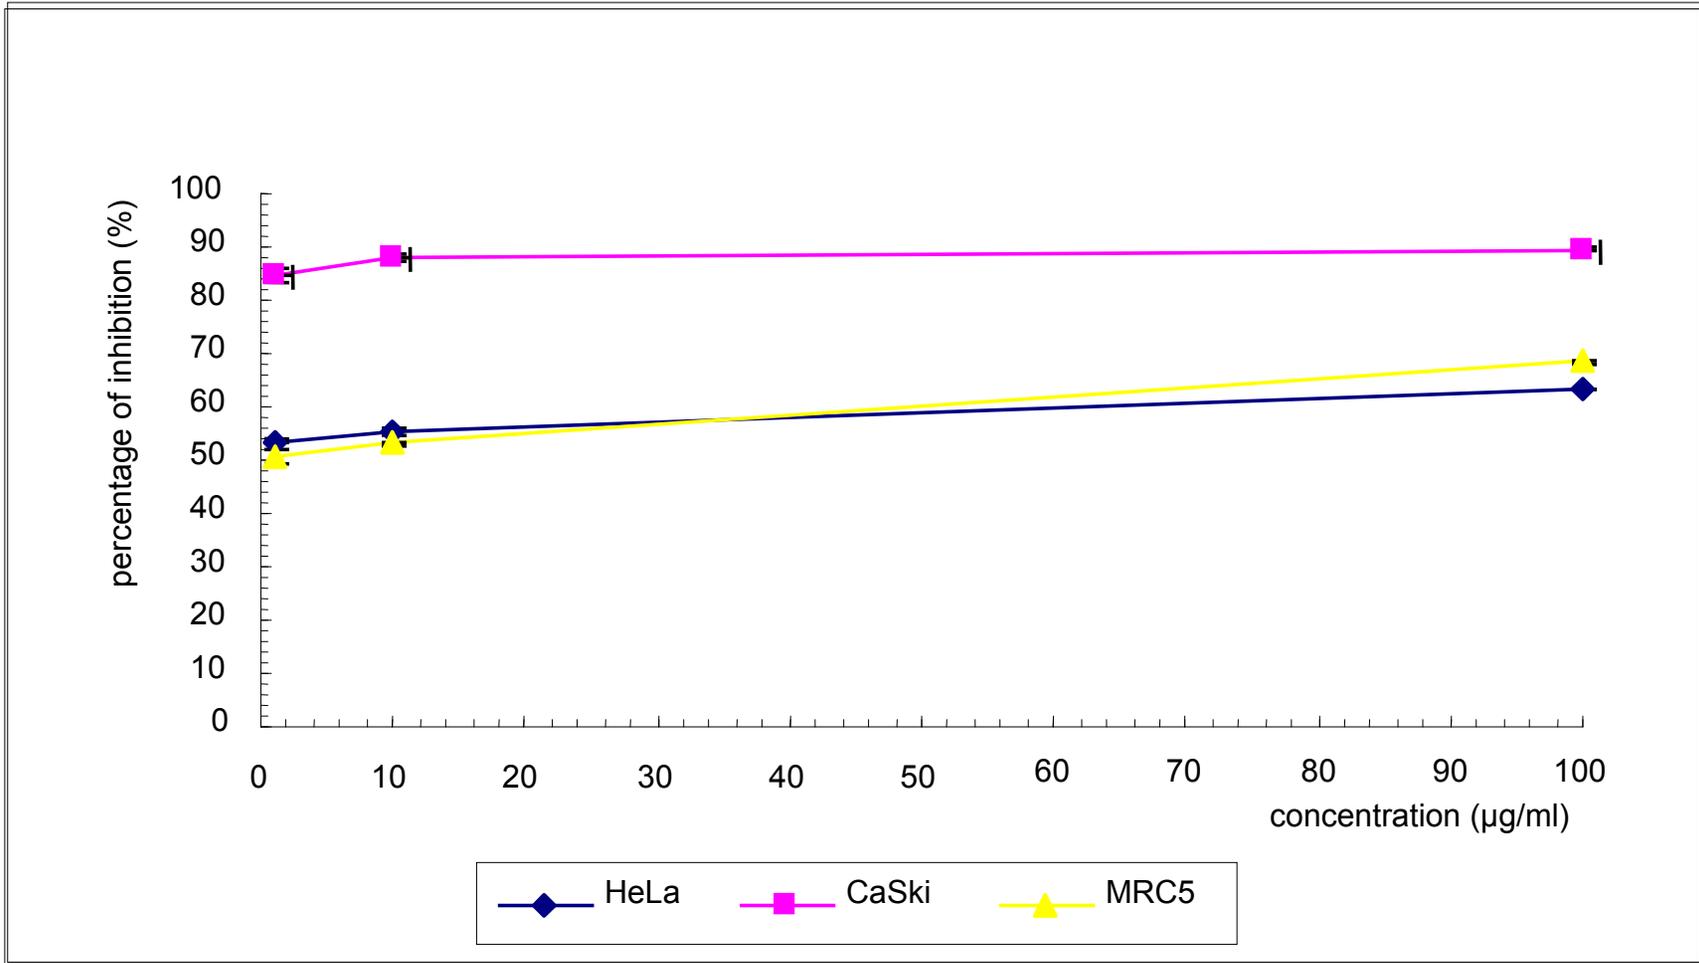

Figure 4.2: Dose-response curve showing *in vitro* growth inhibition of HeLa, CaSki and MRC5 cells by doxorubicin (positive control)

Table 4.3: The IC₅₀ values of doxorubicin against various cell lines

Cell lines	IC ₅₀ value (µg/ml)
HeLa	3.00
CaSki	0.05
MRC5	4.00

4.2.2 *In vitro* Cytotoxic activity of Selected Vegetable Extracts Against HeLa Cells

The *in vitro* growth inhibition of HeLa cells by crude methanol extracts of the 40 vegetables are shown as dose-response curves in Figures 4.3(a) to 4.3(h). The IC₅₀ values were extrapolated from the dose-response curves and summarized in Table 4.4. The inhibition activities ranged from 4.57-41.36% at 1 µg/ml, 9.7-65.66% at 10 µg/ml, 14.95-81.93% at 25 µg/ml, 23.65-84.92 at 50 µg/ml and 28.17-87.78 at 100 µg/ml. Out of 40 vegetables evaluated only 7 vegetables (17.5%) methanol extracts, namely *Capsicum annum* (lada merah), *Capsicum frutescent* (cili padi)s, *Lycopersicum esculentum* (tomato), *Cosmos caudatus* (ualm rajah), *Vigna sinensis* (kacang panjang), *Amaranthus viridis* (bayam merah) and *Ipomoea reptans* (kangkung) were actively cytotoxic against HeLa cell with IC₅₀ values less than 20 µg/ml. The IC₅₀ values are 13 µg/ml, 17.5 µg/ml, 17.4 µg/ml, 18.02 µg/ml, 15.9 µg/ml, 15 µg/ml and 5.9 µg/ml, respectively.

Crude methanol extracts of *Asparagus officinalis* (asparagus), *Solanum tuberosum* (ubi kentang), *Cucumis sativus* (timun), *Cucurbita moschata* (labu merah), *Lagenaria sceraria* (labu ayer), *Momordica charantia* (peria), *Luffa acutangula* (petola segi),

Lactuca sativa (salada), *Neptunia prostrate* (tangki), *Pachyrrizus erosus* (sengkuwang), *Parkia speciosa* (petai), *Amaranthus gangeticus* (bayam pasir), *Apium graveolens* (selder), *Centella Asiatica* (Pegaga), *Daucus carota* (lobak), *Beta vulgaris* (bit), *Citrus aurantifolia* (limau), *Pisum sativum* (kacang putih), *Brassica oleracea* var *alboglabra* (kalian), *Phaseolus vulgaris* kacang buncis), and *Petroselinum crispum* (parsley) possessed inhibited HeLa cells with percentage inhibition less than 50% at all concentrations tested in this study. Therefore, IC₅₀ values could not be determined from the existing dose-response curve

The *in vitro* growth inhibition of HeLa cells by crude water extracts of the 40 selected vegetables are shown as dose-response curves in Figures 4.4(a) to 4.4(h). The

inhibition rates of HeLa cells were 2.00-48.47% at 1 µg/ml, 7.57-51.47 at 10 µg/ml, 11.33-64.44% at 25 µg/ml, 11.63-67.63% at 50 µg/ml and 12.57-72.15% at 100 µg/ml. Only 2 out of 40 crude water extracts of the selected vegetables studied namely, *C. annuum* and *L. sceraria* exhibited IC₅₀ values less than 20 µg/ml and therefore considered actively cytotoxic against HeLa cells (Table 4.5). When compared *L. sceraria* were the more active. The IC₅₀ value for crude water extracts of *L. sceraria* was 6 µg/ml while the IC₅₀ value for crude water extracts of *C. annuum* was 17 µg/ml. On the other hand, *C. frutescens*, *L. esculentum*, *C. moschata*, *C. caudatus* and *V. sinensis*, *A . fistulosum*, *S. grandiflora*, *A. graveolens* and *C. aurantifolia* exhibited no cytotoxic rates against HeLa cells. Their IC₅₀ values ranged from 39.5 µg/ml to 90 µg/ml. The remainder of water extracts exhibited IC₅₀ values greater than 100 µg/ml against HeLa cells.

Generally, from 80 crude methanol and water extracts of selected vegetables studied, only 9 of them exerted active cytotoxic effect against HeLa cells. Both crude methanol and water extracts of *C. annuum* exhibited the active cytotoxic effects against HeLa cells with IC₅₀ values of 13 µg/ml and 17 µg/ml, respectively. The crude methanol extracts of *I. reptans* and the crude water extracts of *L. sceraria* appeared to be more potent as compared to the others due to their abilities to retard more than 50% of cell growth at concentrations lower than as 10wer than 10 µg/ml.

4.2.3 *In vitro* Cytotoxic Activity of Selected Vegetable Extracts Against CaSki Cells

As illustrated in Figures 4.5-4.6, CaSki cells showed different cytotoxic profiles when treated with different crude extracts from selected vegetables. The *in vitro* growth inhibition of CaSki cells by crude methanol extracts of the 40 vegetables are shown as dose-response curves in Figure 4.5(a) to 4.5(h). The IC₅₀ values were extrapolated from the dose-response curves and summarized in Table 4.6. The inhibition activities ranged from 1.39-44.70% at 1 µg/ml, 6.38-70.59% at 10 µg/ml, 14.62-88.94% at 25 µg/ml, 28.36-92.49% at 50 µg/ml, 39.89-93.95% at 100 µg/ml.

Out of 40 vegetables evaluated only 19 vegetables, namely *A. officinalis*, *A. fistulosum*, *S. melongena*, *S. tuberosum*, *Cucurbita moschata*, *L. sceraria*, *A. jiringga*, *N. prostrata*, *V. sinensis*, *P. sativum*, *P. vulgaris*, *A. gangeticus*, *A. viridis*, *H. esculentus*, *A. carambola*, *P. oleracea*, *I. reptans*, *B. vulgaris* and *B. oleracea* var. *alboglabra* were active against CaSki cells with IC₅₀ values less than 20 µg/ml. The IC₅₀ values ranged from 4.9 µg/ml to 19.8 µg/ml.

Crude methanol extracts of *Capsicum annum*, *Lycopersicum esculentum*, *Manihot esculenta* and *Petroselinum crispum* inhibited CaSki cells with percentage of inhibition less than 50% at all concentrations tested in the present study. Therefore, IC₅₀ values could not be determined from the existing dose-response curves.

The *in vitro* growth inhibition of CaSki cells by crude water extracts of the 40 selected vegetables are shown as dose-response curves in Figures 4.6(a) to 4.6(h). The IC₅₀ values were extrapolated from the dose-response curves and summarized in Table 4.7. The results reveal that the water extracts to be cytotoxic of CaSki cells with killing percentages of 4.57-41.36% at 1µg/ml, 9.7-65.66% at 10 µg/ml, 14.95-81.93% at 25 µg/ml, 23.65-84.92 at 50 µg/ml and 28.17-87.78 at 100 µg/ml.

Out of the 40 vegetables evaluated only 11 vegetables water extracts, namely *Asparagus officinalis*, *Capsicum annum*, *Lagenaria sceraria*, *Cosmos caudatus*, *Neptunia prostrata*, *psophocarpus tetragonolobus*, *Parkia speciosa*, *Vigna sinensis*, *phaseolus vulgaris*, *Hibiscus esculentus*, *Portulaca oleracea*, and *Beta vulgaris* were actively cytotoxic against CaSki cells with IC₅₀ values less than 20 µg/ml. The IC₅₀ values ranged were 5.9 µg/ml to 15 µg/ml.

Crude water extracts of *Pachyrrhizus erosus*, *Amaranthus gangeticus*, *Solanum melongena*, *Averrhoa carambola*, *Manihot esculenta*, *Apium graveolens*, *Oenanthe javanica*, and *Citrus aurantifolia* inhibited CaSki cells with percentage of inhibition less than 50% at all concentrations tested in this study. Therefore, IC₅₀ values could not be determined from the existing dose-response curves.

4.2.4 *In vitro* Cytotoxic Activity of Crude Methanol and Water Extracts of Selected Vegetable Against MRC5 Cells

The *in vitro* cytotoxicity activities of crude methanol and water extracts against MRC5 cells are illustrated as dose-response curves in Figures 4.7(a-h) and 4.8(a-h). As before the IC₅₀ values for all crude extracts were extrapolated from the dose-response curves and summarized in Tables 4.8 and 4.9.

Generally, all crude methanol extracts from the 40 selected vegetables demonstrated no cytotoxic activities against MRC5 cells. The killing percentages produced by the methanol extracts ranged from 2.74-32.33 at 1 µg/ml, 8.2-40.20% at 10 µg/ml, 12.46-44.53% at 25 µg/ml, 20.39-50.35% at 50 µg/ml, 25.00-52.98% at 100 µg/ml. Only 8 out of 40 selected vegetable extracts, have IC₅₀ values which could be extrapolated from dose-response curves. The IC₅₀ values extrapolated were between 48 µg/ml to 96 µg/ml produced by *Asparagus officinalis*, *Allium tuberosum*, *A. Centella asiatica*, *Vigna sinensis*, *Capsicum annum*, *Psophocarpus tetragonolobus*, *Solanum melongena* and *Citrus aurantifolia* (Table 4.8). The IC₅₀ values for the other vegetable extracts could not be determined from the existing killing-curves.

The *in vitro* cytotoxicity activities of crude water extracts against MRC 5 cells are illustrated as dose-response curves in Figures 4.8(a)-4.8(h). The IC₅₀ values were extrapolated from the dose-response curves and summarized in Table 4.9. Only 7 out of 40 selected vegetable extracts, have IC₅₀ values which could be extrapolated from dose-response curves. The IC₅₀ values extrapolated which were between 59.5 µg/ml-97.5 µg/ml was produced by *Allium tuberosum*, *A. fistulosum*, *Centella asiatica*, *Vigna sinensis*, *Luffa acutangula*, *Hibiscus esculentus*, *Averrhoa carambola*, *Apium graveolen* and *Citrus aurantifolia*. The IC₅₀ value for the other vegetable extracts could not be determined from the existing killing-curves.

Overall results indicated that, the crude methanol and water extracts from the 40 selected vegetables were found to be not cytotoxic against MRC5 cell lines.

4.3 Anti-HPV 16 E6 Oncoprotein Activity in Selected Vegetable

The crude methanol and water extracts from 10 selected vegetables were analyzed qualitatively for their anti-HPV 16 E6 protein activity in HPV 16-containing cervical cancer-derived cell line, CaSki. The CaSki cells were treated with the vegetable extracts at various concentrations (1, 10, 25, 50 and 100 $\mu\text{g/ml}$) for 3 days. The immunocytochemistry technique, 3-step Indirect Avidin-Biotin Immunoperoxidase with the anti-HPV 16 monoclonal antibody were successfully applied in this study to analyse the expression of E6 HPV 16 oncoprotein in treated and untreated CaSki cells.

Presence or reddish-brownish coloured products in the cytoplasmic and/or nuclear regions indicate expression/ presence of the HPV 16 E6 oncoprotein. The higher the intensity of the coloured products, the higher the amounts of the protein. On the other hand, the lower the amount of E6 simultaneously suggested evidence of suppression by the vegetable extracts. The staining intensity was classified as no stain (-), very weak (+), weak (2+), moderate (3+), strong (4+) and very strong (5+) as illustrated in Figure 4.9.

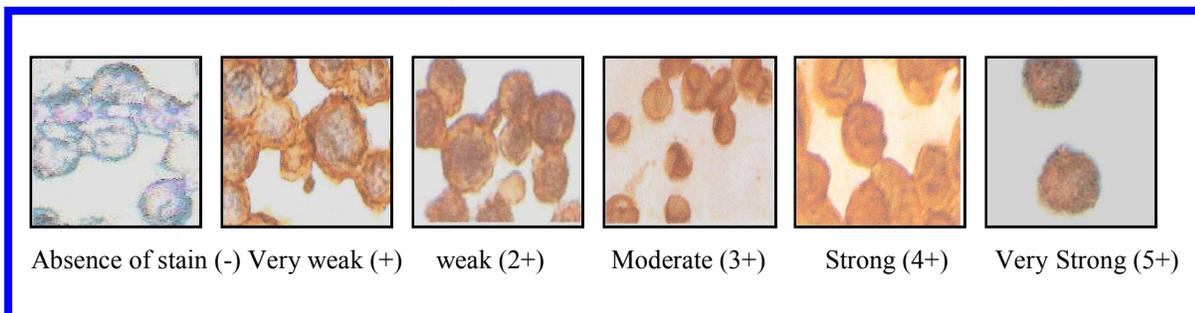

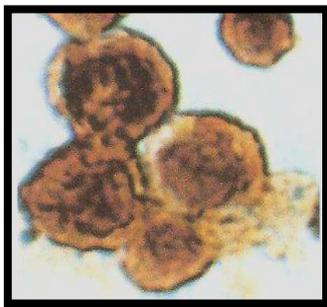

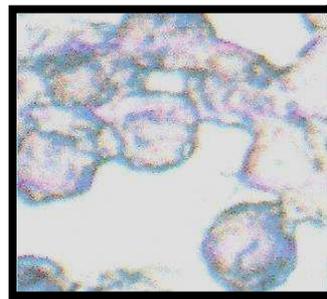

Figure 4.9: Staining intensities of HPV 16 E6 oncoprotein in CaSki cells using the 3-step Indirect Avidin-Biotin Immunoperoxidase methods.

In this present study, two types of negative controls were used. The CaSki cells not treated with the extracts and incubated with anti-HPV 16 E6 monoclonal antibody and CaSki cells not treated with the extracts and not incubated with anti-HPV 16 E6 monoclonal antibody. The staining results for untreated CaSki cells with and without anti-HPV monoclonal antibody are shown in Figures 4.10(a) and 4.10(b). All untreated CaSki cells appeared to be morphologically intact. The negative control incubated with anti-HPV monoclonal antibody exerted very strong reddish-brown stain (5+) due to the detection of high expression of E6 protein while no stain (-) was observed for untreated CaSki cells without incubation with anti-HPV 16 E6 monoclonal antibody

(a)

(b)

Figure 4.10 (a): Untreated CaSki cells incubated with anti-HPV 16 E6 monoclonal antibody. Very strong staining (5+) was observed in the nuclear and cytoplasmic regions (400X)

Figure 4.10 (b): Untreated without incubation with anti-HPV 16 E6 monoclonal antibody. No staining (-) was observed (400X)

Expressions of HPV 16 E6 protein after treatment with varying concentrations of vegetable extracts are shown in Figures 4.11-4.20. The staining intensities of the CaSki cell treated with different extracts at various concentrations were compared with each other and with

the negative control. The morphology of the cells and the intensity of the coloured products were analysed.

4.3.1 *Asparagus officinalis*

As seen in Figure 4.11, the intensity of reddish-brown stain in CaSki cells treated with methanol and water extracts of *Asparagus officinalis* decreased with increasing concentrations of the vegetable extracts. This suggest suppression of HPV 16 E6 oncoprotein in CaSki cells treated with *A. officinalis* extracts at concentration as low as 1 µg/ml. Suppression increased with increasing concentration of the methanol and water extracts of *A. officinalis*.

The methanol extracts of *A. officinalis* produced just a weak suppression of HPV 16 E6 oncoprotein at 1 µg/ml and 10 µg/ml. The suppression increased then on to moderate at 25 µg/ml, strong at 50 µg/ml and became very strong at 100 µg/ml. In contrast, the weak suppression of HPV 16 E6 oncoprotein was observed in CaSki cells treated with water extracts of *A.officinalis* at 1 µg/ml, 10 µg/ml, 25 µg/ml and 50 µg/ml but became very strong at 100 µg/ml.

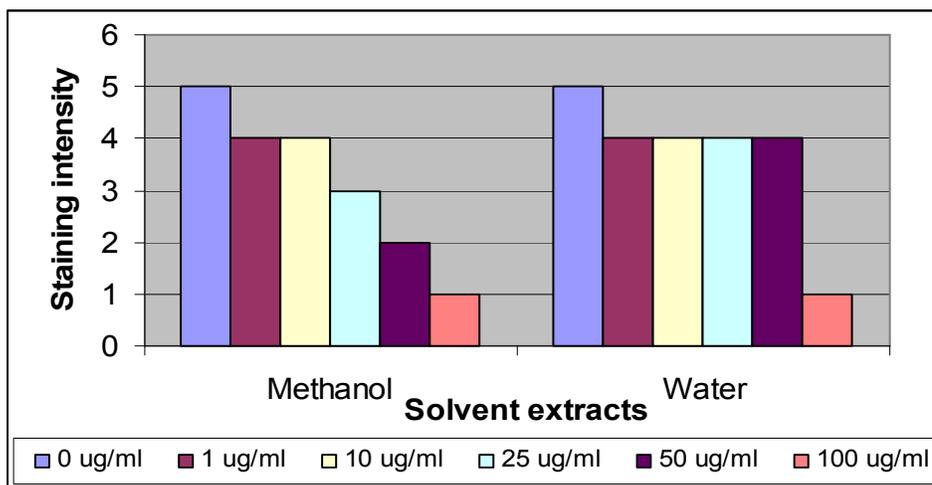

Figure 4.11: Staining intensities of Caski cells treated with *Asparagus officinalis*

Classification for staining intensity as: no stain (0), very weak (1+), weak (2+), moderate (3+), strong (4+) and very strong (5+)

4.3.2 *Beta vulgaris*

Figure 4.12, illustrates a reduction in intensity of the reddish-brown stain in CaSki cells treated with methanol and water extracts of *Beta vulgaris*. The expression of HPV 16 E6 oncoprotein decreased with increasing concentrations of the *B. vulgaris*. The methanol extracts of *B. vulgaris* exhibited moderate suppression of HPV 16 E6 oncoprotein at 1 µg/ml and 10 µg/ml. However from then suppression of HPV 16 E6 in Caski cells treated with methanol extracts of *B. vulgaris* became very strong at 25 µg/ml, 50 µg/ml and 100 µg/ml.

Overall indicated that the water extracts of *Beta vulgaris* was slightly more suppressive against HPV 16 E6 oncoprotein at 10 µg/ml as compared to methanol counterparts. In general, water extracts of *B. vulgaris* exhibited moderate suppression at 1 µg/ml, and stronger at 10 µg/ml and became very strong at 25 µg/ml, 50 µg/ml and 100 µg/ml. CaSki cells treated with *B. vulgaris* extracts remain morphologically intact at all concentrations.

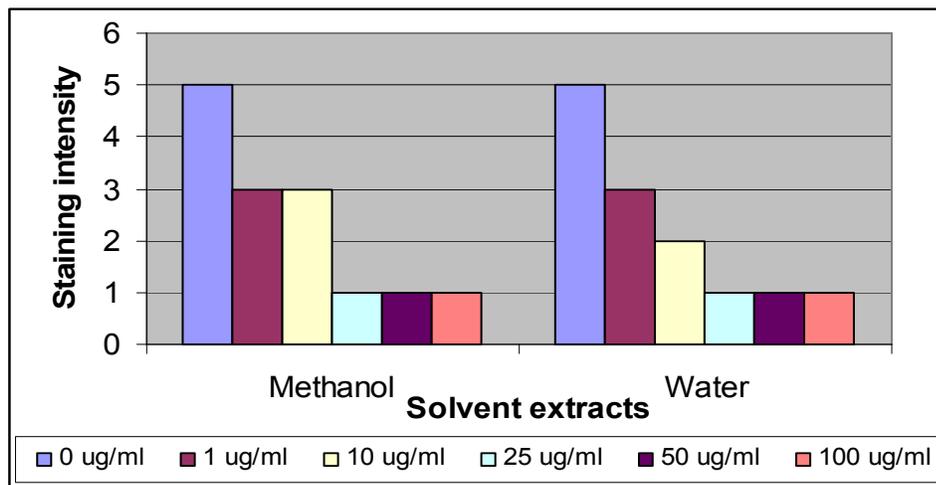

Figure 4.12: Staining intensities of Caski cells treated with *Beta vulgaris*

Classification for staining intensity as: no stain (0), very weak (1+), weak (2+), moderate (3+), strong (4+) and very strong (5+)

4.3.3 *Ipomea batatas*

Figure 4.13 shows that, a reduction in intensity of the reddish-brown stain in CaSki cells treated with methanol and water extracts of *I. batatas*. Expression of HPV 16 E6 oncoprotein decreased with increasing concentrations of *I. batatas* extracts. The methanol extracts of *I. batatas* exhibited very strong suppression of HPV 16 E6 oncoprotein at all concentrations tested.

In contrast, the water extracts of *I. batatas* inhibited weak suppression of HPV 16 E6 oncoprotein at 1 µg/ml and 10 µg/ml but became strong at 25 µg/ml, 50 µg/ml and 100 µg/ml. In general, CaSki cells treated with *I. batatas* extracts remained morphologically intact at all concentrations.

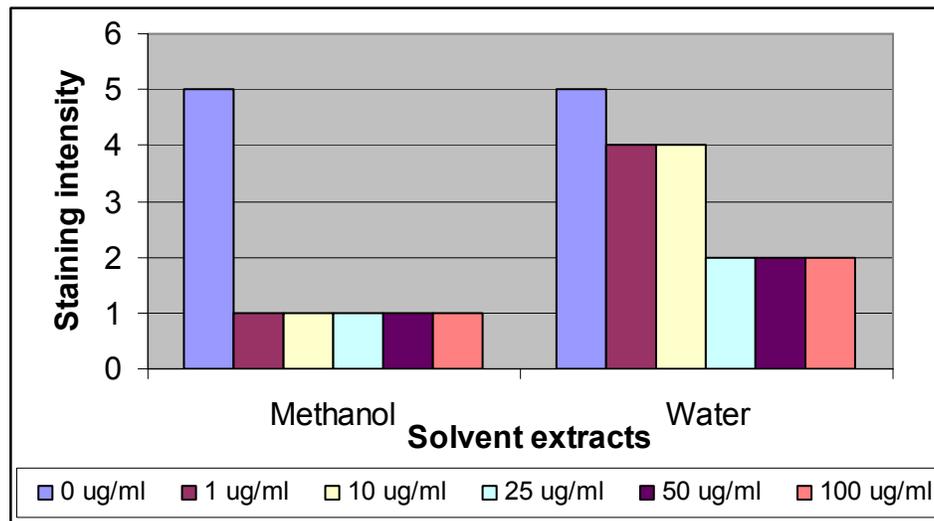

Figure 4.13: Staining intensities of Caski cells treated with *Ipomea batatas*

Classification for staining intensity as: no stain (0), very weak (1+), weak (2+), moderate (3+), strong (4+) and very strong (5+)

4.3.4. *Manihot esculentus*

Figure 4.14, shows that methanol and water extracts of the *M. esculentus* exerted inhibition activity against the HPV-16 E6 oncoprotein. All CaSki cells treated with *M. esculentus* extracts remained morphologically intact at all concentrations used.

In general, the *M. esculenta* extracts demonstrated good inhibition activities against HPV16 E6 oncoprotein in CaSki cells. The methanol extracts of *M. esculenta* exhibited strong suppression of HPV 16 E6 oncoprotein at concentrations 1 $\mu\text{g/ml}$ and 10 $\mu\text{g/ml}$. Suppression of HPV 16 E6 became very strong at concentrations 25 $\mu\text{g/ml}$, 50 $\mu\text{g/ml}$ and 100 $\mu\text{g/ml}$. In contrast, the water extract of *M. esculentus* exhibited strong suppression of HPV 16 E6 oncoprotein at all concentrations tested.

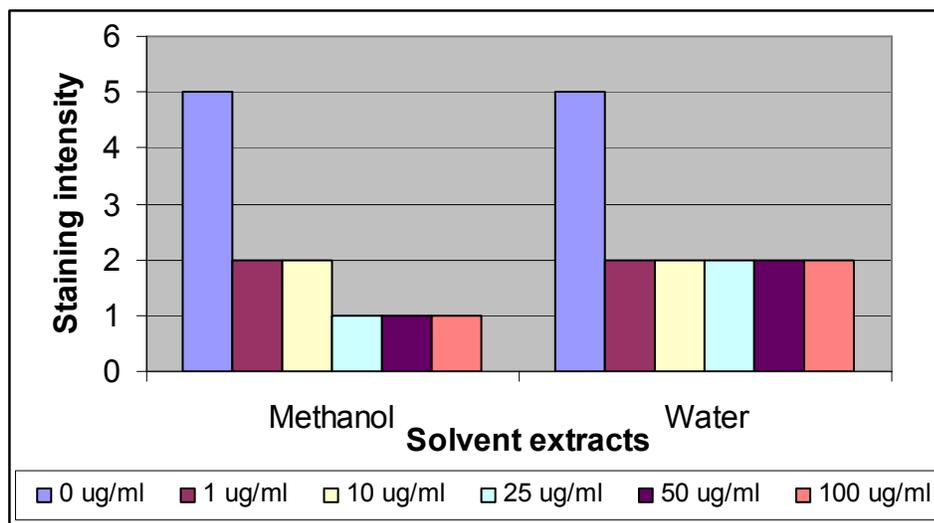

Figure 4.14: Staining intensities of Caski cells treated with *Manihot esculentus*

Classification for staining intensity as: no stain (0), very weak (1+), weak (2+), moderate (3+), strong (4+) and very strong (5+)

4.3.5 *Pachyrrizus erosus*

Figure 4.15 show that, the intensities of reddish-brown stain decreased with increasing concentrations of methanol and water extracts of *P. erosus*. This shows that the expression of HPV-16 E6 oncoprotein in CaSki cells reduced when the concentration of *P. erosus* extracts increased. Overall results showed that the reddish brown stain was seen in both nuclear and cytoplasmic regions of CaSki cells. The methanol extract of *P. erosus* produced no suppression of HPV 16 E6 at 1 $\mu\text{g/ml}$, but produced weak suppression at 10 $\mu\text{g/ml}$. The suppression increased then on to moderate at 25 $\mu\text{g/ml}$ and became strong at 50 $\mu\text{g/ml}$ and 100 $\mu\text{g/ml}$.

In contrast, the water extract of *P. erosus* exhibited moderate suppression inhibition of HPV 16 E6 oncoprotein at concentrations as low as 1 $\mu\text{g/ml}$. Suppression of HPV 16 E6 became strong at 10 $\mu\text{g/ml}$ and 25 $\mu\text{g/ml}$. The inhibition became very strong then on at concentrations 50 $\mu\text{g/ml}$ and 100 $\mu\text{g/ml}$. The CaSki cells treated with methanol extract started to lysie at concentrations 25 $\mu\text{g/ml}$ to 100 $\mu\text{g/ml}$. In contrast, the CaSki cells remained morphological intact when treated with water extracts at all of concentrations used.

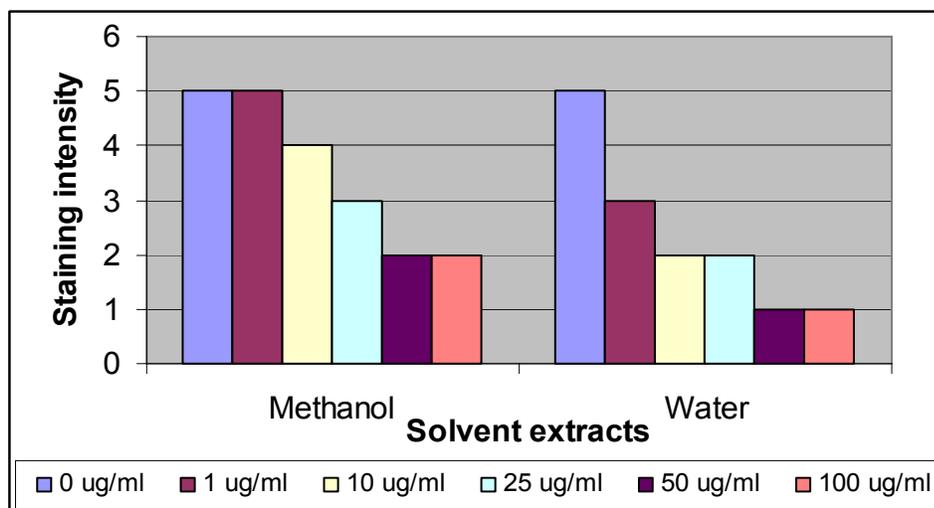

Figure 4.15: Staining intensities of Caski cells treated with *Pachyrrizus erosus*

Classification for staining intensity as: no stain (0), very weak (1+), weak (2+), moderate (3+), strong (4+) and very strong (5+)

4.3.6 *Petroselinum crispum*

As seen in Figure 4.16, there is reduction in intensity of the reddish-brown stain at concentrations as low as 1 $\mu\text{g/ml}$ for methanol and water extracts of *P. crispum*. Very weak suppression of HPV 16 E6 oncoprotein was observed in CaSki cells treated with methanol extracts at all concentrations tested and in CaSki cells treated with water extracts at concentrations 1 $\mu\text{g/ml}$, 25 $\mu\text{g/ml}$ and 50 $\mu\text{g/ml}$. The suppression of HPV 16 E6 protein became moderate in cells treated with 100 $\mu\text{g/ml}$ of the water extract. The integrity of CaSki cells treated with *P. crispum* extracts were negatively affected where the cells lysed at concentrations as low as 1 $\mu\text{g/ml}$ (for methanol and water extract) and 10 $\mu\text{g/ml}$. The distribution of stain was observed either in the cell cytoplasm only or both nucleus and cytoplasm.

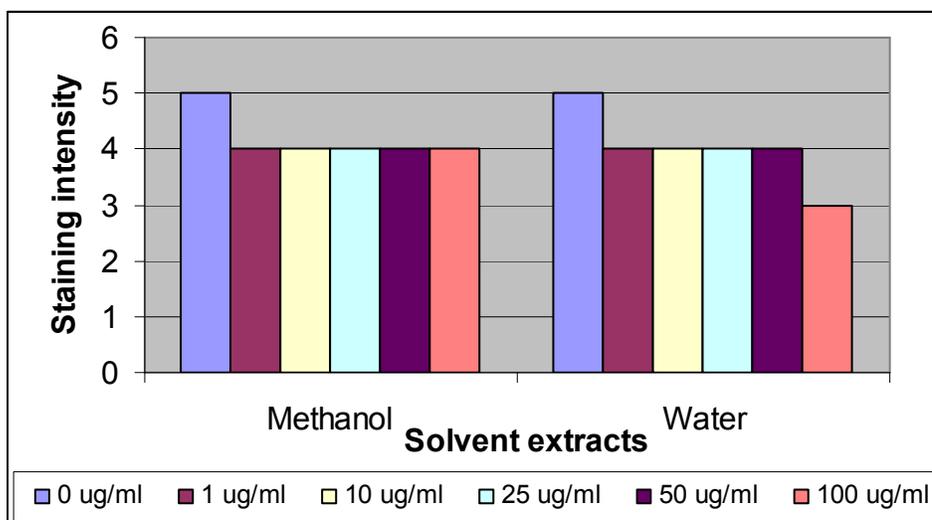

Figure 4.16: Staining intensities of Caski cells treated with *Petroselinum crispum*

Classification for staining intensity as: no stain (0), very weak (1+), weak (2+), moderate (3+), strong (4+) and very strong (5+)

4.3.7 *Phaseolus vulgaris*

Figure 4.17, illustrates that the methanol extract of *P. vulgaris* exhibited very strong suppression of HPV 16 E6 at 1 $\mu\text{g/ml}$ and 10 $\mu\text{g/ml}$. However, the suppression weakened from then on resulting in the reddish-brown stain to become stronger with increasing concentrations of the *P. vulgaris* methanol extract.

In contrast, the water extracts did not exhibit any suppression of HPV 16 E6 oncoprotein at 1 $\mu\text{g/ml}$ and 10 $\mu\text{g/ml}$. Weak suppression was seen at 25 $\mu\text{g/ml}$, suppression of HPV 16 E6 become strong at 50 $\mu\text{g/ml}$ and very strong at 100 $\mu\text{g/ml}$. Cell lysis was observed at 1 $\mu\text{g/ml}$ for water extracts and at concentration as low as 25 $\mu\text{g/ml}$ for methanol extracts.

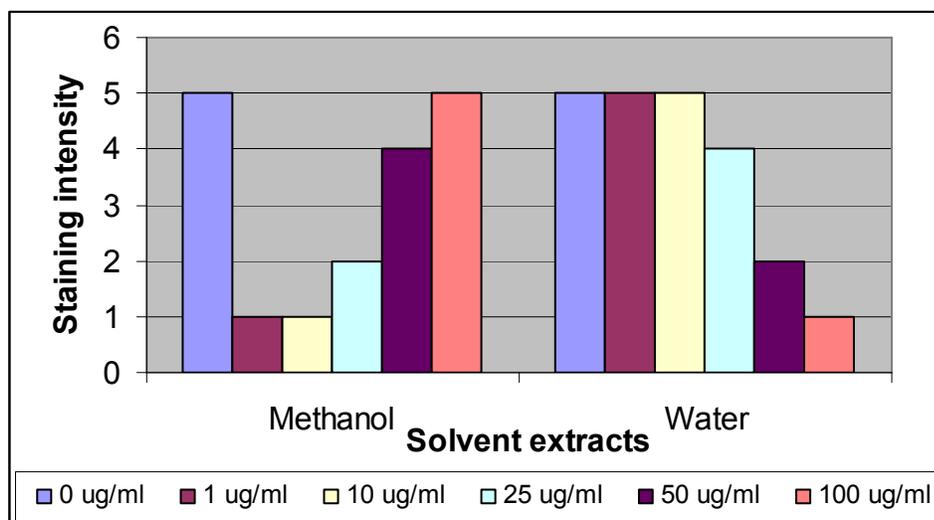

Figure 4.17: Staining intensities of Caski cells treated with *Phaseolus vulgaris*

Classification for staining intensity as: no stain (0), very weak (1+), weak (2+), moderate (3+), strong (4+) and very strong (5+)

4.3.8 *Portulaca oleracea*

The resulting staining intensity of CaSki cells treated with *Portulaca oleracea* extracts are shown in Figure 4.18. In general, the *P. oleracea* extracts demonstrated good inhibition activities against HPV16 E6 oncoprotein in CaSki cell. The methanol extract of *P. oleracea* very strongly suppressed HPV 16 E6 oncoprotein at concentrations 1 $\mu\text{g/ml}$, 10 $\mu\text{g/ml}$ and 25 $\mu\text{g/ml}$. However, the inhibition weakened a little (though still strong) at concentrations 50 $\mu\text{g/ml}$ and 100 $\mu\text{g/ml}$.

In contrast, the water extract of *P. oleracea* produced strong inhibition of HPV 16 E6 oncoprotein at concentrations as low as 1 $\mu\text{g/ml}$ and 10 $\mu\text{g/ml}$. The inhibition then became very strong at higher concentrations. All the CaSki cells treated with *P. oleracea* extracts appeared to

be morphologically intact. Overall results showed that the reddish brown stain was seen in both nuclear and cytoplasmic regions.

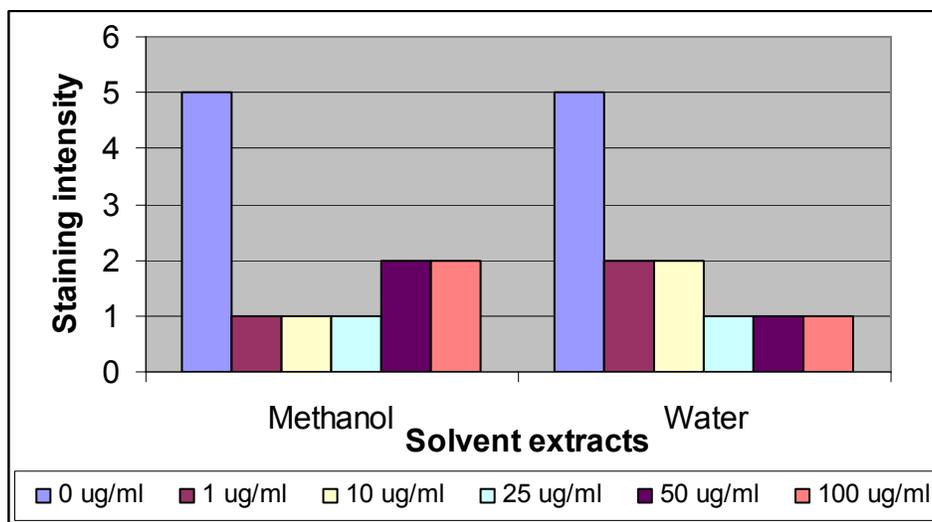

Figure 4.18: Staining intensities of Caski cells treated with *Portulaca oleracea*

Classification for staining intensity as: no stain (0), very weak (1+), weak (2+), moderate (3+), strong (4+) and very strong (5+)

4.3.9 *Sesbania grandiflora*

As denoted by the reduction of reddish-brown stain in CaSki cells, the inhibition activities of HPV 16-E6 oncoprotein by *S. grandiflora* extracts increased with the increasing concentrations of the extracts (Figure 4.19). The methanol extract of *S. grandiflora* produced a strong inhibition of HPV 16 E6 oncoprotein at concentrations as low as 1 $\mu\text{g/ml}$ and remained consistent at concentrations 10 $\mu\text{g/ml}$ and 25 $\mu\text{g/ml}$. The inhibition became very strong from then on at concentrations 50 $\mu\text{g/ml}$ and 100 $\mu\text{g/ml}$.

In contrast the water extract of *S. grandiflora* produced a weak suppression of HPV 16 E6 at 1 $\mu\text{g/ml}$. The suppression increased then on to moderate at 10 $\mu\text{g/ml}$, strong at 25 $\mu\text{g/ml}$

and 50 µg/ml and became very strong at 100 µg/ml. Evident here that methanol extract produced a greater inhibition effects as compared to water extract. The integrity of CaSki cells were negatively affected where the cells lysed after treated with methanol at 25 µg/ml and 50 µg/ml.

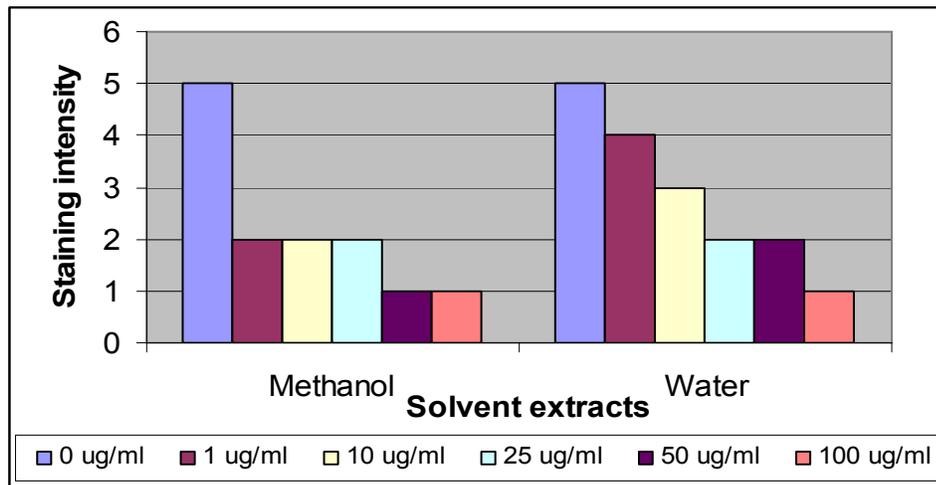

Figure 4.19: Staining intensities of CasKi cells treated with *Sesbania grandiflora*

Classification for staining intensity as: no stain (0), very weak (1+), weak (2+), moderate (3+), strong (4+) and very strong (5+)

4.3.10 *Solanum tuberosum*

The resulting staining intensity of the CaSki cells treated with *Solanum tuberosum* extracts are shown in Figure 4.20. The decrease in staining intensity was observed in CaSki cells treated with increasing concentration of the extracts. This indicates that the *S. tuberosum* extracts inhibited the expression of HPV 16 E6 oncoprotein in a dose-dependent manner, where the suppressing effects increased with increasing concentration of the extracts.

The water extracts of *S. tuberosum* exerted a more suppressive effect against HPV-16 E6 oncoprotein as compared to methanol extracts. Both extracts exerted weak suppressing effects against HPV 16 E6 oncoprotein at concentrations 1 µg/ml and 10 µg/ml. However, from then on CaSki cells treated with water extracts exhibited very weak reddish brown stain, indicating very strong suppression at concentrations, 25 µg/ml, 50 µg/ml and 100 µg/ml. Methanol extracts of *S. tuberosum* on the other hand produced just moderate suppression of the oncoprotein at concentrations, 25 µg/ml, 50 µg/ml and 100 µg/ml. The integrity of CaSki cells treated with *S. tuberosum* extracts were negatively affected where the cells lysed at concentration as low as 25 µg/ml (for methanol extract).

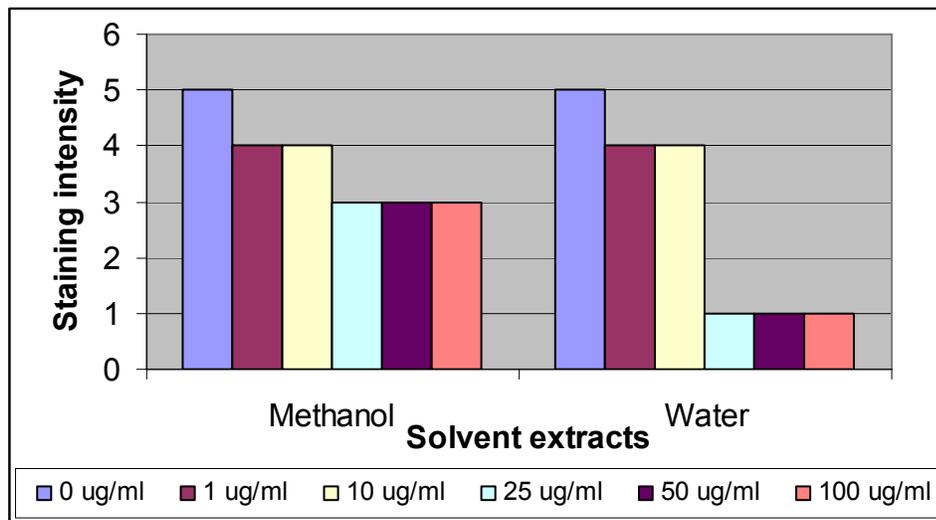

Figure 4.20: Staining intensities of Caski cells treated with *Solanum tuberosum*

Classification for staining intensity as: no stain (0), very weak (1+), weak (2+), moderate (3+), strong (4+) and very strong (5+)

4.4 Comparison of Anti-HPV 16 E6 Oncoprotein Activity in Selected Vegetable

Twenty crude extracts (methanol and water) from ten selected vegetables were analyzed qualitatively for possible anti-HPV 16 E6 oncoprotein activity. The staining intensity of coloured products was observed in CaSki cells treated with the selected vegetable crude extracts indicated that each vegetable extracts possess different ability in suppressing the expression of HPV 16 E6 oncoprotein (Figure 4.21 and Figure 4.22).

Overall results indicate that not all of the vegetable extracts suppressed the HPV 16 E6 oncoprotein in a dose-dependent manner where greater inhibition activity against E6 oncoprotein was observed in higher extract concentration.

Ten out of 20 extracts (50%) were found effective in suppressing the HPV 16 E6 oncoprotein at the lowest extract concentration (25 µg/ml and below) used in this study. They were both methanol and water extracts for *P. oleracea*, *I. batatas*, *M. esculentus*, methanol extract for *P. erosus*, *B. vulgaris*, *S. grandiflora* and water extracts for *A. officinalis*.

Overall results indicated that *P. oleracea* extracts was the most effective in suppressing the HPV 16 E6 oncoprotein. When compared, water extracts was better than methanol extracts at suppressing the HPV 16 E6 oncoprotein.

Appearance of CaSki cells after treatment with methanol extract of *Asparagus officinalis*

	Concentration of extracts (µg/ml)	Morphology of cells	Intensity of reddish-brown stain
	100	Intact	+
	50	Majority intact but some showing lysis	2+
	25	Majority intact but some showing lysis	2+
	10	Intact	4+
	1	Intact	4+
