Candidate statement

I, Nazirah Hasnan, hereby declare that this submission is my own work and that it contains no material previously published or written by another person, except where acknowledged in the text. Nor does it contain material which has been accepted for the award of another degree.

In addition, ethical approval from the Human Research Ethics Committee of the University of Sydney and Medical Ethics Committee of the University of Malaya Medical Centre were granted for the studies presented in this thesis. Participants were required to read a participant information document and informed consent was gained prior to data collection.

Abstract

Spinal cord injury (SCI) adversely affects the physiological functions of most organ systems resulting in restrictions in performance of daily activities and social participation. Depending on the level of injury, SCI individuals can be amongst the most physically deconditioned of individuals with a disability. SCI renders profound effects on fitness, exercise capacities and health. There is increased risk of developing secondary health conditions such as cardiovascular disease and diabetes in chronic SCI survivors.

There is good evidence that exercise is effective for improving physical fitness and general health in the SCI population. Leg exercise is usually restricted because of paralysis after SCI and upper body exercise is not as beneficial as lower body exercise due to the relatively small muscle mass in the arms. Technological advancements have allowed functional electrical stimulation (FES) muscle contractions to enable exercise for the paralysed lower limbs of persons with SCI. Other technologies including virtual reality (VR) approaches have also begun to be deployed as exercise and rehabilitation strategies in recent years.

This thesis comprised of three studies, which examined exercise outcomes involving the use of assistive technologies (FES and VR) for exercise testing and training in persons with SCI.

The acute physiological response of FES-assisted cycling exercise was first assessed comparing the different exercise modalities that were available for people with SCI. These

were arm crank ergometry (ACE), FES–leg cycle ergometry (FES-LCE), ACE+FES-LCE and an integrated arm and FES-leg tricycle. It was found that combined arm and leg (hybrid) FES cycling exercise could develop higher oxygen uptake and cardiovascular demand compared to ACE or FES-LCE alone. Hybrid FES cycling evoked up to 148% higher oxygen uptake, 49% greater cardiac output and 47% higher heart rate than FES-LCE during steady-state exercise thereby concluding that FES-LCE by itself was insufficient to promote aerobic fitness and training benefit in people with SCI.

Based on the findings of the first experiment, the acute physiological and psychological responses to hybrid FES cycling were then further assessed in different exercise environment i.e. natural outdoor and simulated VR-enhanced indoor environment. With only 5% and 1% difference in the cardiorespiratory and perceptual-psychological responses respectively between the two modes, it was concluded that indoor and outdoor modes have similar exercise “dose-potency” and self-perceived effort.

Following these experiments on acute responses, a final study which examined the fitness, carbohydrate and lipid metabolisms and psychological outcomes following a 6-week high intensity interval training employing hybrid FES cycling training was carried out. The study demonstrated greater aerobic fitness by 16% and increased muscle mass by 6%. The 6-week training resulted in 60-80% improvement in negative mood states and up to 76% increase in post-exercise positive feeling states. However there was a lack of change in their lipid profile and glucose metabolism.

The importance of incorporating regular physical activity and exercise into the lifestyle of people with SCI is evident. The studies conducted herein identified the best exercise modality; propose strategies for enhancement of exercise participation and highlight the benefits of exercise in this population.

Abstrak

Kecederaan saraf tunjang menyebabkan terjejasnya kebanyakan fungsi fisiologi sistem organ badan. Pesakit-pesakit ini mengalami kurang-upayaan dalam melaksanakan aktiviti harian dan penyertaan sosial. Bergantung kepada tahap kecederaan, mereka yang mengalami kecederaan saraf tunjang adalah antara yang mengalami ketidakupayaan dan dekondisi fizikal yang paling teruk. Kecederaan saraf tunjang menyebabkan kesan yang mendalam terhadap kecergasan, kapasiti senaman dan kesihatan. Terdapat juga peningkatan risiko untuk berlakunya komplikasi perubatan sekunder seperti penyakit jantung dan kencing manis.

Terdapat bukti bahawa senaman adalah berkesan untuk meningkatkan kecergasan fizikal dan kesihatan umum pesakit kecederaan saraf tunjang. Senaman menggunakan kaki adalah terhad kerana kelumpuhan selepas kecederaan saraf tunjang. Senaman melibatkan anggota atas badan tidak begitu bermanfaat seperti senaman menggunakan anggota bawah badan kerana jisim otot yang agak kecil pada lengan. Kemajuan teknologi terkini membolehkan “functional electrical stimulation” (FES), suatu teknik rangsangan saraf dan otot dengan menggunakan elektrik untuk membolehkan senaman menggunakan kaki bagi golongan ini. Pendekatan teknologi lain termasuk teknologi realiti maya “virtual reality” (VR) telah mula digunakan sebagai strategi senaman dan pemulihan dalam tahun-tahun kebelakangan ini.

Tesis ini terdiri daripada tiga kajian yang melihat respon semasa menjalani aktiviti senaman yang melibatkan penggunaan teknologi dalam menyokong ujian senaman dan latihan bagi orang yang mengalami kecederaan saraf tunjang.

Kajian pertama melibatkan penilaian respon akut semasa subjek-subjek menjalankan senaman FES-cycling, di mana perbandingan respon di antara modaliti senaman telah dijalankan. Modaliti tersebut adalah “arm crank ergometer” (ACE), functional electrical stimulation-leg cycle ergometry” (FES-LCE), ACE+FES-LCE dan basikal roda tiga yang telah diintegrasikan dengan pedal lengan dan unit FES. Hasil kajian menunjukkan bahawa penggabungan senaman lengan dan kaki (hybrid FES cycling) dapat meningkatkan permintaan kardiovaskular dan pengambilan oksigen yang tinggi berbanding dengan ACE atau FES-LCE sahaja. Hybrid FES cycling menghasilkan sehingga 148% penggunaan oksigen, 49% keluaran jantung dan 47% degupan jantung yang lebih tinggi dari hanya menggunakan modaliti FES-LCE semasa menjalankan ‘steady-state exercise’. Dengan itu dapat dirumuskan bahawa senaman menggunakan modaliti FES-LCE sahaja adalah tidak mencukupi untuk mempromosikan kecergasan aerobik dan mendapat faedah senaman yang sewajarnya untuk golongan yang mengalami kecederaan saraf tunjang.

Berikutan hasil dari kajian yang pertama, kajian seterusnya melibatkan penilaian akut respon psikologi dan fisiologikal terhadap hybrid FES cycling semasa menjalankan senaman di persekitaran luar dan di persekitaran dalam yang menggunakan teknologi realiti maya. Dengan hanya perbezaan sebanyak 5% dan 1% pada respon kardiorespirasi dan persepsi psikologi masing-masing, dapat dirumuskan bahawa persekitaran dalam atau luar memberi kesan yang sama dari segi “dose-potency” dan usaha senaman.

Berikutan eksperimen yang melibatkan gerakbalas akut, kajian terakhir melibatkan penilaian pencapaian dari segi kecergasan, metabolisme karbohidrat dan lipid serta psikologi selepas menjalani program “high-intensity interval training” menggunakan hybrid FES

cycling selama 6 minggu. Kajian ini telah menunjukkan peningkatan kecergasan aerobik sebanyak 16% dan penambahan jisim otot sebanyak 6%. Latihan selama 6 minggu mengakibatkan penambahbaikan sebanyak 60-80% keadaan mood negatif dan sehingga 76% peningkatan perasaan positif selepas menjalani senaman. Walaubagaimanapun, terdapat tiada perubahan dalam profil lipid dan metabolisme glukosa.

Kepentingan menjadikan aktiviti fizikal secara berkala dan senaman sebagai gaya hidup orang-orang yang mengalami kecederaan saraf tunjang telah terbukti. Kajian-kajian yang telah dijalankan telah mengenalpasti modaliti senaman yang terbaik; mencadangkan strategi untuk meningkatkan penyertaan dalam senaman dan menonjolkan manfaat senaman pada golongan ini.

Acknowledgements

الْحَمْدُ لِلَّهِ رَبِّ الْعَالَمِينَ

Praise be to God for giving me the inspiration to embark on this journey and providing me the wisdom, strength and courage to complete this thesis.

This thesis would not have been possible without the contribution of many great people and it gives me great pleasure to thank them.

Firstly, I would like to thank my supervisors Prof Ruby Husain and Prof Glen Davis for accepting my candidature, for believing in my ideas and me and for their unwavering support throughout the candidature. Prof Ruby, I treasure your patience, kindness and dedication. You have been so generous with your guidance and encouragement throughout this long and winding journey, you have shown that you truly cared and it meant a lot to me. Glen, I thank you for making a scientist out of a clinician. I had doubts that it could be done initially but you have shown me the way. I am grateful to you. Thanks for sharing your expertise in the area of clinical exercise sciences. Your boundless vigour, enthusiasm, passion and constant guidance on research have no doubt kept me going throughout, despite the ups and downs that have been my constant companion. I will not forget the contributions of A/Prof James Middleton as my co-supervisor during my time in Sydney.

I would like to acknowledge the support I received from the University of Malaya and the University of Sydney for the scholarship and study grants provided. My sincere appreciation goes to Prof Rosmawati Mohamed and Assoc Prof Kamila Ghazali for their support in realizing my Cotutelle PhD candidature. My heartfelt appreciation also goes to Dr. Che Hashim of ULPA, UM for his invaluable assistance.

To my CERU family at Lidcombe, thank you for the friendship, intellectual exchange and crazy banter. My laboratory experience was anything but dull and lonely. Nalan, Ricardo, Iza, and Vanesa, thanks for being there always. Azah, Eduardo, Camila, David and Scott, it was great having you as part of my research experience. Che, my FES guru, thanks for the trouble-shooting backup. Many thanks to Mr. Ray Patton, for I could not have done my experiments without his technical and problem-solving support.

I must also thank my extended family in Sydney; Nora, Zaed, Ely, Yazid, Sue, Azhar, Hana, Pojie, Intan, Hugo, Zakiah, Saifol, Azzah, Kak Ana, Amira, Yanti, Fendi, Patrick, John, Azman, Ruby; and their families; for making my family's overseas experience an enriching and memorable one.

My colleagues at the Department of Rehabilitation Medicine, UM, I truly appreciate your support. To everyone at the UM and UniSyd offices who have helped me along the way, thank you very much for your assistance.

My rehab medicine mentor, Prof Dato' Zaliha Omar, thanks for your encouragement and love. To my rehabilitation medicine fraternity in Malaysia, there is much to do and we must rise to the challenge. I thank you for your friendship and support.

My girlfriends who have motivated me throughout this journey... Zuri, Amy and Zaf, I can't thank you enough for your support and putting up with my panic attacks, tears and hysterics. Many thanks Amy for proof reading this thesis.

To my mother, Jamaliah Mahmud, thank you for your love, support and doa. My brothers Zul, Jim, Ridzhal and Radzif, this is for our late father, thanks for being there for me to make this happen. To my in-laws, thank you for your support and understanding.

My beloved husband, Ibez, I could not have done this without you. Thank you for your love, friendship and sacrifice. I am truly blessed. To my beautiful children, Danial, Alia, Ezra and Jenna, my PhD journey was your journey too. You are my inspiration. Thank you for your love, patience, understanding and allowing me to complete this thesis.

Lastly, I would like to express my deepest gratitude to all the research subjects involved in my research in Sydney, Australia and Kuala Lumpur, Malaysia. You gave so much of your time and effort; I thank you for your commitment. You have provided me not just with a research experience but also a personal and greater insight into the lives of persons with spinal cord injury.

Terminology

The following terms and their meanings were adopted and consistently used during this thesis:

Assistive technology

Referred to any item, piece of equipment, or product system, whether acquired commercially, modified or customized that is used to maintain, increase, or improve the functional capabilities of individuals with disabilities (United States Assistive Technology Act of 2004)(Pennsylvania, 2012).

Complete injury

This term was used when there was an absence of sensory and motor function in the lowest sacral segments (S4-S5) (i.e. no sacral sparing) (Kirshblum et al., 2011).

Electrical stimulation

Within the context of this manuscript, electrical stimulation referred to the process of eliciting muscular contractions elicited via electrical impulses arising from skin surface electrodes placed over neuromuscular motor points of muscles. The electrical impulses then artificially stimulate muscular contractions via the motor nerves innervating the selected muscle groups.

Exercise

Referred to a series of physical activity, which is structured, planned and repetitive (Caspersen, Powell, & Christenson, 1985).

Functional Electrical Simulation

Functional electrical stimulation (FES) is the application of external electrical current to produce muscle contractions, by neuromuscular stimulator, thereby bypassing the central nervous system (Holsheimer, 1998).

Functional Electrical Simulation Leg Cycle Exercise (FES-LCE)

Functional electrical stimulation leg cycle exercise referred to involuntary movements of the gluteal, quadriceps and hamstring muscle groups whereby stimulus was sequenced during appropriate angle ranges of the cycle ergometer pedals. The endpoint of this stimulation sequence was the non-voluntary performance of a cycling motion.

Health promotion

Process of enabling people to increase control over the determinants of health and thereby to improve their health (World Health Organisation, 1986).

Hybrid

In this manuscript, the term ‘hybrid’ was used to describe concurrent arm and leg exercise, whereby leg exercise was evoked by functional electrical stimulation leg cycle exercise

Incomplete injury

This term was used when there was preservation of any sensory and/or motor function below the neurological level that included the lowest sacral segments S4-S5 (i.e. presence of “sacral sparing”). Sensory sacral sparing includes sensation preservation (intact or impaired) at the anal mucocutaneous junction (S4-S5 dermatome) on one or both sides for

light touch or pin prick, or deep anal pressure (DAP). Motor sacral sparing included the presence of voluntary contraction of the external anal sphincter upon digital rectal examination (Kirshblum et al., 2011).

Mechanical efficiency

Mechanical efficiency is usually used for human motor efficiency in terms of power produced for oxygen consumed. Higher efficiency (economy) is associated with better results achieved in various activities and sport disciplines. The mechanical efficiency in chosen motoric actions ranged from 2% to 80% depending on the working limb, amount and duration of work, types of performed exercises (eccentric, concentric, mixed), types of sport discipline practiced, type of muscles fibres involved or the calculation methods (Jobson, Hopker, Korff, & Passfield, 2012).

Mechanical efficiency – Gross mechanical efficiency

Gross mechanical efficiency was defined as the ratio between external power output (PO) and energy expenditure (de Groot et al., 2005).

Mechanical efficiency – Net mechanical efficiency

Net efficiency considered only that portion of the energy expenditure, which contributed directly to external work. Therefore with net efficiency excludes resting energy expenditure .

Neurological level of injury (NLI)

Referred to the most caudal segment of the spinal cord with normal sensory and antigravity

motor function on both sides of the body, provided that there is normal (intact) sensory and motor function rostrally. The segments at which sensory and motor testing show normal function is found often to on different sides on the body. Thus, up to four different segments may be identified in determining the neurological level, i.e., R(ight)-sensory, L(eft)-sensory, R-motor, L-motor. The single NLI refers to the most rostral of these levels (Kirshblum et al., 2011).

Paraplegia

Referred to impairment or loss of motor and/or sensory function in the thoracic, lumbar or sacral (but not cervical) segments of the spinal cord, secondary to damage of neural elements within the spinal canal. With paraplegia, arm functioning is spared, but, depending on the level of injury, the trunk, legs and pelvic organs may be involved. The term is used in referring to cauda equina and conus medullaris injuries, but not to lumbosacral plexus lesions or injury to peripheral nerves outside the neural canal (Kirshblum et al., 2011).

Physical activity (PA)

Referred to any bodily movement produced by skeletal muscles that results in a reasonable amount of energy expenditure (Caspersen et al., 1985).

Spinal Cord Injury (SCI)

Spinal cord injury is a trauma to the spinal cord resulting in a change, temporary or permanent, in its motor, sensory and autonomic function (American Spinal Injury Association, 2000).

Secondary health conditions

Secondary health conditions are causally related to a disabling condition (i.e., occurs as a result of the primary disabling condition, in this context; spinal cord injury) and can be pathology, impairment, a functional limitation, or an additional disability. These conditions can be either of a physical or a psychosocial nature (Wyatt & White, 2000).

Tetraplegia

Referred to impairment or loss of motor and/or sensory function in the cervical segments of the spinal cord due to damage of neural elements within the spinal canal. Tetraplegia typically results in impairment of function of all four extremities as well as the trunk and pelvic organs. It does not include brachial plexus lesions or injury to peripheral nerves outside the neural canal (Kirshblum et al., 2011).

Virtual reality

Referred to a range of computing technologies that present artificially generated sensory information in a form that people perceive as similar to real-world objects and events (Wilson, Foreman, & Stanton, 1997).

Abbreviations

| | |
|-----------------|---|
| ACE | Arm crank ergometer |
| ACSM | American College of Sports Medicine |
| AD-ACL | Activation-deactivation adjective checklist |
| ADL | Activities of daily living |
| AHA | American Heart Association |
| ANOVA | Analysis of variance |
| ASIA | American Spinal Injury Association |
| BMI | Body mass index |
| BWSTT | Body weight supported treadmill training |
| $(Ca-Cv)O_2$ | Arterio-venous oxygen difference |
| CO ₂ | Carbon dioxide |
| CHD | Coronary heart disease |
| CVD | Cardiovascular disease |
| ECG | Electrocardiogram |
| EIFI | Exercise-induced feeling inventory |
| ES | Electrical stimulation |
| FES | Functional electrical stimulation |
| FES-LCE | Functional electrical stimulation–leg cycle ergometer |
| FRE | Framingham Risk Equation |
| GPS | Global positioning system |
| HD | High definition |
| HDL | High-density lipoprotein |

| | |
|-------------------|--|
| HIIT | High-intensity interval training |
| HR | Heart rate |
| HR _{max} | Maximal heart rate |
| HRR | Heart rate reserve |
| ISNCSCI | International Standard for Neurological and Functional Classifications of Spinal Cord Injury |
| LDL | Low-density lipoprotein |
| LMN | Lower motor neuron |
| ME | Mechanical efficiency |
| ME _G | Gross mechanical efficiency |
| ME _N | Net mechanical efficiency |
| OGTT | Oral glucose tolerance test |
| PA | Physical activity |
| PO | Power output |
| Q | Cardiac output |
| QUEST | Quebec user evaluation of assistive technology |
| RER | Respiratory exchange ratio |
| RPE | Rating of perceived exertion |
| SCI | Spinal cord injury |
| SCORE | Systematic Coronary Risk Evaluation |
| SD | Standard deviation |
| SE | Standard error |
| SV | Stroke volume |
| TG | Triglycerides |

| | |
|---------------------|---------------------------------------|
| TM | Treadmill |
| TPR | Total peripheral resistance |
| UMN | Upper motor neuron |
| VCO ₂ | Carbon dioxide production |
| VE | Expired ventilation |
| VO ₂ | Oxygen uptake |
| VO _{2peak} | Peak oxygen uptake |
| VR | Virtual reality |
| VRSQ | Virtual reality symptom questionnaire |
| W | Watt |

Units of measure

| | |
|--|--|
| b | beats |
| $\text{b}\cdot\text{m}^{-1}$ | beats per metre |
| $\text{b}\cdot\text{min}^{-1}$ | beats per minute |
| cm | centimetre |
| d | day |
| $\text{d}\cdot\text{wk}^{-1}$ | day per week |
| deg | degree |
| g | gram |
| $\text{g}\cdot\text{s}^{-1}\cdot\text{count}^{-1}$ | gram per second per count |
| Hz | hertz |
| kg | kilogram |
| L | litre |
| $\text{L}\cdot\text{min}^{-1}$ | litre per minute |
| m | metre |
| mA | milliampere |
| MET | metabolic equivalent |
| $\text{MET}\cdot\text{min}\cdot\text{wk}^{-1}$ | metabolic equivalent per minute per week |
| min | minute |
| $\text{min}\cdot\text{d}^{-1}$ | minute per day |
| $\text{min}\cdot\text{wk}^{-1}$ | minute per week |
| mL | millilitre |
| $\text{mL}\cdot\text{b}^{-1}$ | millilitre per beat |

| | |
|--|------------------------------------|
| $\text{mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ | millilitre per kilogram per minute |
| $\text{mL}\cdot\text{min}^{-1}$ | millilitre per minute |
| $\text{mL}\cdot 100\text{min}^{-1}$ | millilitre per 100 minute |
| $\text{m}\cdot\text{min}^{-1}$ | metre per minute |
| $\text{mmol}\cdot\text{L}^{-1}$ | millimole per litre |
| ms | millisecond |
| μs | microsecond |
| $\text{rev}\cdot\text{min}^{-1}$ | revolution per minute |
| s | second |
| W | Watt |
| wk | week |
| y | year |
